DR. ROGERS. May I ask why she had bleeding from the gastrointestinal tract and in the urine?

DR. MALLORY. I do not know about the urine. As far as the gastrointestinal tract is concerned the jaundice is adequate. I think two-thirds of our jaundice cases show a positive guaiac.

A PHYSICIAN. What did the kidneys show?

DR. MALLORY. Nothing of note beyond arteriolar sclerosis. The kidneys in some cases of cholemia do show marked change of the tubules but not often red cells. The glomeruli ordinarily are perfectly normal.

DR. CHESTER M. JONES. I should like to ask how common it is to get sharp pain radiating to the top of the shoulder in this sort of picture. That is very interesting and might fit in with an intrahepatic condition rather than gallbladder itself.

DR. ROGERS. Yes. If it were from the gallbladder I think you would expect it in the back rather than the shoulder.

DR. ALLEN. This second attack suggested perforation of the gallbladder with irritation under the diaphragm. I suspected that that was what they were going to find at operation.

CASE 22082

PRESENTATION OF CASE

A forty-one year old Russian woman was admitted complaining of blood in her stools

About a year before entry the patient noticed a considerable amount of clotted blood in her stools on several occasions associated with slight pain. This continued off and on for about six months until she consulted a physician who removed or cauterized something in the rectum. She did not know what was found but thought that it was not a hemorrhoid and was higher up in the rectum. There was no change in her condition thereafter. She had been constipated for about five years and had required one or two laxative tablets daily until three weeks before entry when presumably her bowel movements occurred spontaneously about once daily. She felt as though she had incomplete evacuation and there was a lower abdominal cramping sensation occasionally associated with the frequent passage of flatus. The character of the stools was not noted. There was a loss of about five pounds in one year. Her catamenia was regular but the onset of the menses was usually marked by pain in the left lower quadrant. There was some leukorrhea in the interval between periods.

A plastic operation upon the left tube with suspension of the uterus had been done eleven years previous to entry.

Physical examination showed a middle-aged woman who appeared to be in no distress. Oral hygiene was poor and there were many carious teeth. The heart was normal. The blood pressure was 115/75. The lungs were clear. A well healed lower midline abdominal scar was observed. The inguinal nodes appeared to be slightly enlarged. There was slight tenderness with deep pressure in the left lower quadrant. Vaginal examination showed a large, firm, nodular, lacerated cervix. A small, pale, cystic nodule was present on one lip. The fundus was slightly enlarged and fixed to the anterior abdominal wall. The left vault felt full and was slightly indurated and tender.

The temperature, pulse, and respirations were normal.

Examination of the urine was negative. The blood had a hemoglobin of 70 per cent.

A barium enema showed a shadow in the sigmoid near its junction with the descending colon. The shadow was about 3 centimeters in diameter and appeared to be polypoid in configuration.

A proctoscopy showed a bleeding growth high in the rectosigmoid. At the end of six days an exploratory laparotomy was done.

DIFFERENTIAL DIAGNOSIS

DR REGINALD H SMITHWICK The history is that of a forty-one year old female apparently

in good general health. What little evidence is available concerning the blood picture suggests a slight degree of anemia.

The history of clotted blood in her stools on several occasions during the past year suggests a profuse type of intermittent bleeding which might be seen, and which would be more apt to be seen in some highly vascular friable lesion which might ulcerate at times containing an excellent blood supply, and suggests that the bleeding is from above the internal sphincter inasmuch as the blood must have been in the rectum for some time in order to produce clots. This type of bleeding is not characteristic of carcinoma. The patient's age is against a carcinoma of the sigmoid. Profuse bleeding in carcinoma of the sigmoid is rare at any age, and the history of removal of some type of growth in the rectum or sigmoid six months ago plus the x-ray findings of a definite polypoid lesion in the sigmoid, plus the proctoscopic examination in which a lesion was actually seen, places the tumor in the sigmoid colon.

There is a discrepancy between the barium enema and the proctoscopic finding. The proctoscope would place the growth low in the sigmoid, whereas the barium enema would place the growth high in the sigmoid. This story suggests that the growth is polypoid and has a pedicle of some length so that the tumor can at times be visible from below and can at times be forced high enough to appear at the junction of the sigmoid and descending colon by x-ray.

The history also suggests a partial degree of intestinal obstruction, as evidenced by lower abdominal cramps, the passage of flatus, and the sense of incomplete evacuation after movement. This suggests a fairly large polypoid tumor producing partial obstruction of the intestine. There are many benign lesions of the large intestine, many of which are not commonly seen, such as lipomata, fibromata, fibromyomata, etc. Sarcoma is very rare. Invasion of the rectum or sigmoid by tumors of the pelvic organs is possible but would not be apt to give this particular group of signs and symptoms. The most likely possibility would seem to be a polyp of the sigmoid composed to a large degree of epithelial elements with a rich blood supply on a long pedicle and presumably benign at this time, although malignant degeneration at the base is always a possibility.

PREOPERATIVE DIAGNOSES

First operation Carcinoma of the rectum

Second operation Polyp of the sigmoid

DR REGINALD H SMITHWICK'S DIAGNOSIS

Benign polyp of the sigmoid

PATHOLOGIC DIAGNOSIS

Adenomatous polyp of the sigmoid

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY. Dr. Smithwick's reasoning which led him to the diagnosis of benign polyp in this case was very good and I am particularly impressed by his use of the two apparently conflicting statements in regard to the location of the lesion as supplied by proctoscopy and by the barium enema. The anatomic findings bore him out completely in this respect since the polyp was found to have a pedicle nearly 2 cm. in length. At the time of the proctoscopy a biopsy was done and was reported by the laboratory as characteristic of a benign adenomatous polyp. Biopsy reports of this sort should, however, always be taken with a certain amount of reservation since an infiltrating tumor often undermines the normal mucosa for a considerable distance and biopsy taken apparently from the tumor mass may actually contain none of the tumor.

The patient was explored by Dr. Lantou who found a freely movable polypoid mass which he

could palpate within the sigmoid. He noted that it could be moved up and down for a distance of about four inches. The base of the pedicle was too low to do a Mikulicz operation so he felt that a two-stage procedure was wisest and limited himself at that time to a cecostomy. She did well following this procedure and two weeks later the polyp with six inches of the adjacent sigmoid was resected and an end-to-end anastomosis was done. At the time of the exploration it was noted that she also had a fairly large fibroid of the uterus, but since this was causing no symptoms it seemed wisest to leave it alone.

The final pathologic examination showed a typical adenomatous polyp with no atypicality of the epithelium and no evidence of invasion. Why a tumor of this type should produce evidence of intestinal obstruction is not evident at first glance. A sufficient number of them, however, are found which have produced intussusception to make it seem possible that this may be the mechanism.

ANDREW BORDE, PERIPATETIC PHYSICIAN

ONE of the most remarkable of the sixteenth century English physicians was Andrew Borde (or Boorde), whom Anthony à Wood¹, the Oxford biographer, described as having "a lambling head, and an unconstant mind", which he used, nevertheless, not unprofitably, while traveling 'through and round about Christendom, and out of Christendom' This "cheery, frank, bright, helpful, and sensible fellow", according to Furnivall², was born near Cuckfield, Sussex, about 1490 Brought up in Oxford, he spent twenty years of his life in the Carthusian order, strictly adhering to vegetarianism and fasting Breaking away from the monastic life before the age of forty, the rest of his days were devoted to travel and study France and Spain he visited many times, returning at intervals to publish his books in England

"I study and piactyce physyk," he wrote, "for the sustentacyon of my lyuyng" The study took place at Montpelier, foremost university of its time in France, Borde practiced in all the countries he visited His chief English patrons were Henry VIII and Cromwell, each sent him abroad, probably as a reward for personal services

Back in Winchester, where he had inherited some property, he fell foul of "a Calvinistical bishop", who accused him of breaking his vow of chastity Poor Borde, whom Wood calls "a noted Poet, a witty and ingenious Person, and an excellent Physician of his time", was thrown into the Fleet prison and there died in 1549, perhaps by poisoning himself Such was the sad earthly end of *Andreas Perforatus*, as he styled himself, who, in Furnivall's estimate, was "sound at the core, a pleasant companion in many of England's most memorable days, worthy, with all his faults, of respect and regard"³

Borde's writings, esteemed by his contemporaries, are now widely sought for by all The British Museum collection is outstanding, the Boston Medical Library prizes three rare editions, two of the "Breviarie of Health" and one of the "Dietarie of Health" His most important book, "The fyrst Booke of the Introduction of Knowledge", with its delightful woodcuts, is available to scholars in the Furnivall reprint of 1870 In this book we find Borde's descriptions of his travels in France, Spain, Italy, Egypt, Barbary and Turkey, as well as throughout England Little misses his searching eye In passing through Spain, for instance, he comes to a church at St Domingo in which are kept a white cock and a hen He unearths the fable of the miracle connected with these birds, a tale recently beautifully retold by Mr Henry Thomas⁴ of the British Museum Skeptical Borde, who made it his business "to se and to know the trewth of many thynges", was shriven by "an auneynt doctor of dyuynite", who admitted that many of the clergy deceived the people about miracles and shrines containing the bones of saints In spite of Borde's seeing through the trick of this particular miracle, he failed to persuade pilgrims from England and Scotland, whom he met in his travels, from making the pilgrimage When all nine of the pilgrims died and only Borde got back to Aquitaine, he "dyd kas the ground for 10y", as well he might

THE AMERICAN FOUNDATION OF TROPICAL MEDICINE

THE American Academy of Tropical Medicine, meeting in St. Louis in November, founded The American Foundation of Tropical Medicine, for the prevention, control and scientific investigation of the tropical diseases which occur in the continental United States and the neighboring countries around the Caribbean Sea. The purposes of the foundation will be made effective by a fund which private individuals and commercial concerns with interests in the tropics have agreed to raise.

Dr Earl B McKinley, dean of the Medical School of George Washington University will represent the academy on the board of directors, other directors being Dr Isaiah Bowman president of Johns Hopkins University, Perry Burgess, president of the American Leprosy Foundation, Dr Nicholas Murray Butler president of Columbia University, E B De Golia of San Francisco, Harvey S Firestone Thomas W Lamont, Dr Leo S Rowe, director general of the Pan American Union, Dr Robert G Sproul, president of the University of California, Malcolm B Stone of Boston president of the Ludlow Manufacturing Associates and Alvin P Howard and Paul H Saunders of New Orleans.

At the same meeting Dr Richard P Strong head of the School of Tropical Medicine of Harvard University, was elected president of the Academy.

The days of private and presumably disinterested philanthropy are drawing farther from us, fewer are the great fortunes which depression and taxation have left in a condition to indulge in outstanding benevolences. More and more we must rely upon commercial interests to endow scientific investigation and humanitarian endeavors, and on the whole these endowments have been made with a generosity of spirit which leaves science free to seek its ends with an unencumbered honesty of purpose.

The Massachusetts Medical Society

THE ANNUAL MEETING OF THE SECTION OF PEDIATRICS

THE Section of Pediatrics will present, at the annual meeting in June, a panel discussion on "Rheumatism and Rheumatic Heart Disease in Early Life." The leader of the panel will be Dr John Lovett Morse of Boston. Dr Morse is Emeritus Professor of Pediatrics of Harvard Medical School and was for many years Physician in Chief of the Infants' and Children's Hospitals of Boston. Assisting Dr Morse on the panel will be Doctors Paul White, Tracy Mal-

lory Hyman Green, T Duckett Jones and Eli Friedman of Boston and Oliver Stansfield of Worcester.

The meeting of the Section will start promptly at 9 A.M. on Wednesday, June 10, 1936, in the lower room of the Springfield Municipal Auditorium. Adequate loud speakers will be installed so that the discussion may be heard clearly in all parts of the room.

The etiology, pathology, symptomatology, prognosis and treatment of "Rheumatism and Rheumatic Heart Disease in Early Life" will be discussed by the panel. Questions in writing may be submitted in advance to Dr Morse or to your officers, and from the floor at the meeting.

Plan now to attend the annual meeting of The Massachusetts Medical Society at Springfield and especially the Section of Pediatrics. We know you will enjoy the entertainment in store for you. Bring the ladies and make it a three day vacation of fellowship, instruction and fun.

HYDATID MOLE

Hydatid mole consists of the formation of cysts from a millimeter to 2.5 cm in diameter

*A series of short selected articles by members of the Section is being published weekly
Comments and questions by subscribers are solicited and will be discussed by members of the Section.

in the placenta. When it occurs early in pregnancy the whole placenta may be involved with disappearance of the fetus and continued growth of the mole. It may occur at any time during pregnancy with only parts of the placenta involved and a normal fetus. In such cases the disease is probably often not recognized. The cysts are filled with a thin clear fluid. The important change so far as the clinician is concerned is a proliferation of the epithelial layers of the placenta, Langhans' cells and the syncytium, because it may become malignant, forming chorio-epithelioma.

The cause of hydatid mole is not known. It is estimated to occur about once in 2000 pregnancies and at any age in the reproductive life.

Suspicion of the disease should be aroused by a greater increase in the size of the uterus than the normal for the period of gestation at which the patient is examined. That and bleeding coming on usually at from the second to the sixth month of pregnancy are the outstanding symptoms. Some of the cysts may be passed so that an attempt to find them should be made under such conditions. The disease commonly results in expulsion of the mole during the third or fourth month of gestation. Any spontaneous miscarriage might be due to a mole and the products should always be examined at least grossly and preferably microscopically as well.

The treatment consists of being sure that the uterus is emptied and that can be done only by examination under anesthesia with exploration of the uterine cavity with the finger, ovum forceps, and curette. More than ordinary gentleness is necessary because the villi may have invaded the uterine wall making soft areas, easily perforated.

The treatment must not end there because it is estimated that in five per cent of these cases chorio-epithelioma may develop from the mole and it has to be diagnosed early if the patient is to be saved. This disease may appear soon or years after the mole. The patient should be kept under observation for two years. During the first year an Aschheim-Zondek test should be done at frequent intervals. It becomes negative normally in from two to four weeks after the uterus is empty. If a positive test persists, chorio-epithelioma must be suspected and the uterus curetted for diagnosis and the vaginal wall examined for metastases. A microscopic examination of the tissue removed is essential. If irregular bleeding (especially that characterized by gushes of blood) occurs, the uterus should be curetted for diagnosis.

A PRIZE FOR AN APPROVED ESSAY

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding a rotating internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1935-1936.

This report is to be typewritten and when completed is to be sealed unsigned, in a plain envelope, which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope and sent to

The Massachusetts Medical Society
Committee on Medical Education and Medical Diplomas,
8 Fenway Boston Mass

The contest this year closes May 1 1936. Reports may be submitted at any time prior to that date.

THE PHYSICIAN IN NATIONAL DEFENSE

Editor, *New England Journal of Medicine*

Believe it or not, the Constitution as interpreted by the courts makes every male citizen between the ages of eighteen and forty-five a member of the unorganized militia. If this were not so the guarantee of life liberty and the pursuit of happiness would be a farce. In a great national emergency all of us must help and it behooves each of us to find his proper place in the complicated machinery of national defense before the emergency arises—even before it appears upon the horizon. The more we desire peace the more important this is. The most effective way to preserve peace is to prepare against war. In joining the Army and Navy we identify ourselves with the most potent peace agencies in the country with men who picture the terrible effects of war from memory not from imagination.

The various elements of national defense open to physicians should be considered in logical order.

First the Regular Army or Navy as a life career. The requirements of the Regular Army are American citizenship, age between twenty-three and thirty-two, compliance with physical standards satisfactory evidence of good character, degree of M.D. from a Class "A" Medical School and a diploma from the National Board of Medical Examiners or passage of a satisfactory mental examination. The successive grades and pay under present laws in the Regular Army are as follows:

Grade	Time in Grade	Pay Proper (Monthly)
1st Lieutenant	3 years	\$166.67
Captain	9 years	\$210.00-\$230.00
Major	8 years	\$300.00-\$350.00
Lt. Colonel	6 years	\$379.17-\$408.33
Colonel	Until age 64	\$460.07-\$500.00

Brigadier General and Major Generals are selected from grade of Colonel and receive more pay and allowances.

In addition to the above pay from \$18 to \$54 per month, depending upon the number of dependents, is paid in lieu of subsistence. Quarters are furnished in kind or are commuted into money allowances in amounts varying from \$40 to \$120 a month depending upon rank. No officer below the grade of Brigadier General receives total pay and allowances exceeding \$600 per month.

The Regular Army is an interesting life career free from the irritating commercial details of civilian practice. It is hard to enter and will never make you rich but if it appeals to you write to the Corps Area Surgeon, Army Base Boston Mass.

Secondly We should consider seeking a commission in the National Guard of our State. Information about it can be secured from the nearest State Armory or from the Adjutant General of the State.

Finally If we do not feel that we can ally ourselves with either of these sections of the first line of defense, we should certainly endeavor to join the second line, namely, the Army or Navy Reserve Qualifications (Army) American citizenship, age between twenty one and thirty five years, satisfactory physical examination, diploma from a Class "A" Medical School, a license to practice medicine in a state, territory or the District of Columbia or a diploma from the National Board of Medical Examiners, and actual engagement in the ethical practice of medicine Reserve Officers receive no pay except when ordered to active duty They are never ordered to active duty in time of peace without their consent. When on active duty they receive the same pay as regular officers of the same grade Their promotion is more rapid than that of the regular army

The reason for the existence of the Reserve, which, by the way, was originated by the Medical Corps, is the need of a large body of officers assigned and partially trained in advance of a possible emergency It will contribute enormously to the efficiency of mobilization and will materially lessen confusion and woe-pulling for desirable rank and assignment One of the advantages to the individual officer is that he will receive promotion during peace time and will not have to enter the service in war time in the lowest grade In return for these advantages, however, a reserve officer is expected to devote a small amount of time to his own military education You are assured, however, that the training is too interesting to be burdensome, and cannot but be valuable to you in your civilian careers

Newly appointed Reserve Lieutenants will be very likely to have an opportunity to be ordered to active duty with the Civilian Conservation Corps at a total salary approximating \$225 a month, if they so desire Since the expenses are very low, this is an excellent opportunity to save up a little money to start practice

The Reserve is rapidly undergoing a transformation New life is being breathed into it. It is expected that in the near future the medical regiments, the medical detachments and the hospitals of all sizes will have their commissioned personnel slots filled and that participation in their activities will be both pleasant and interesting instead of being merely a duty For information write to the Corps Area Surgeon, Army Base, Boston, Mass

The three components of national defense are now before you You can do one of the following things

Throw this article into the pile of things you have finished with

Put it aside for further consideration and probably forget it

Act

G M EKWURZEL, Colonel, M C,
Corps Area Surgeon,
Army Base, Boston, Mass

RECENT DEATHS

BERRY—JOHN CUTTING BERRY, M.D., of 28 Trowbridge Street, Worcester, Massachusetts, died February 8, following a brief illness Dr Berry was born at Small Point, Maine, in 1847, the son of Stephen Decatur Berry, a ship captain

His early education was acquired at Monmouth Academy and Bowdoin College He received his M.D. degree from Jefferson Medical College in 1871 and immediately afterward served as a medical missionary under a commission from the American Board of Foreign Missions Especial interest in medicine led to an appointment in a government hospital at Kobe, Japan, and outlying clinics One evidence of personal influence is shown in reforms in Japanese prison administration Dr Berry later had positions in Okayama and Kyoto and became influential in many ways in that country, having founded the Doshisha Hospital and with it the training school under Miss Laura Richards Distinction in connection with his work in the earthquake area in 1891 and in various other ways secured recognition which led to the decoration of "The Imperial Order of the Sacred Treasure of the Third Class"

On returning to the United States in 1893 after a period of study in Vienna, he settled in Worcester, where he established a large practice in eye and ear surgery, in addition to serving on the staff of the Worcester City Hospital Membership in the Massachusetts Medical Society and Fellowship in the American Medical Association were acquired in 1896

His standing in his chosen field led to membership in the New England Ophthalmological Society and the New England Society of Otology and Laryngology

Dr Berry retained his interest in the development of Japan and was active in civic and religious circles in Worcester

Three children Dr Gordon Berry of Worcester, Miss Katherine Fiske Berry, also of Worcester, and Mrs Helen Berry Holton, of Brockton, survive him, as do two grandchildren

KNOWLES—WILLIAM FLETCHER KNOWLES, M.D., a retired member of the Massachusetts Medical Society, died at his home, 1035 Beacon Street, Brookline, Massachusetts, February 12, 1936

Dr Knowles was born in Cambridge, Massachusetts, in 1861 the son of William Fletcher Knowles and Sarah (Robinson) Knowles After graduating from the Harvard Medical School in 1895, he served first at the Carney Hospital and later at the Massachusetts Eye and Ear Infirmary, and was a member of the American College of Surgeons and formerly President of the New England Oto-Laryngological Society

During the War, Dr Knowles served at the base hospital at Camp Devens and received the commission of major

He is survived by his widow, Mrs Charlotte Treat

knowles a son Robert T. Knowles of Okmulgee Oklahoma a daughter Mrs. G. Gardner Monks and a sister Miss Carrie W. Knowles, of Boston

NOTICES

SUMMER COURSE IN BACTERIOLOGY

A summer course in General and Sanitary Bacteriology will be offered this year by the Department of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, Mass. The course will last for six weeks from June 16 to July 28. Classes will meet daily except Saturdays and Sundays, from 9 to 12.

The course will consist of lectures, recitations, demonstrations, laboratory work and appropriate field trips. The laboratory work will include consideration of the methods employed in studying bacteria, the preparation and sterilization of culture media and other laboratory supplies, the study of pure cultures, the effect of physical and chemical agents of bacteria and the bacteriological examination of water and milk.

The course is designed for beginners in bacteriology and should appeal to public health nurses, health education workers, public health laboratory and hospital technicians, sanitary inspectors, water works operators, milk inspectors, milk analysts and students preparing for careers in biological science, public health or medicine. Preliminary training in science though desirable is not required. The fee for the course is \$55.00.

Academic credit will be given to all who pass the course successfully.

Students having adequate training and special interests may arrange to work on special problems most suited to their needs.

All inquiries should be addressed to Prof. M. P. Horwood, Massachusetts Institute of Technology who will be in charge of the course.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday February 27 in the Amphitheatre of the Peter Bent Brigham Hospital Dr. James E. Paullin, Clinical Professor of Medicine, Emory University, Atlanta, Georgia, Physician in Chief, pro tempore Peter Bent Brigham Hospital will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12, staff rounds will be conducted.

A SECONDHAND DEAN LEWIS LOOSE LEAF SURGERY WANTED

Dr. Mildred E. Burton a medical missionary in the Clara Swain Hospital, Bareilly India under the Board of the Women's Foreign Missionary Society of the Methodist Episcopal Church wishes to purchase a secondhand Dean Lewis Loose Leaf Sur-

gery which has been kept up to date. Anyone wishing to dispose of the same kindly communicate with Mrs. Wm. S. Mitchell, 100 Washington Street, Malden, Mass.

REPORTS AND NOTICES OF MEETINGS

GREATER BOSTON MEDICAL SOCIETY

The January meeting of the Greater Boston Medical Society was held on January 7, 1938 at the Beth Israel Hospital. The president of the society Dr. H. Linenthal presided.

Dr. Elliott P. Joslin opened the meeting with a brief talk on the Community Drive, which is a combination of over one hundred social agencies, and spoke warmly in favor of its appeal for financial aid. He also presented a case of diabetes who had been treated with a new kind of insulin the action of which is greatly prolonged because of its combination with the protamine of a certain fish.

Dr. Harry Blotner spoke on the "Effect of Intestinal Enzymes on Insulin: Prevention of Digestion of Insulin with Alcohol." He attempted to discover the reason why insulin is ineffective by mouth. By incubating insulin with gastric juice and injecting it into rabbits he found that the insulin had become inactive. If however he added alcohol before incubating the insulin was no longer digested by the gastric juices and its activity remained. The same was found to be true using the enzymes trypsin and also pancreatin. With these experimental data in mind he gave insulin with alcohol by mouth to a patient but found that the blood sugar was not affected. This may be because the alcohol is absorbed from the stomach leaving the insulin unprotected against the gastric juice or because the mucous membrane of the intestine is impermeable to insulin.

Dr. Boris Greenberg spoke on "The Visualization of Postgonorrheal Complications." By injecting Iliodol into the urethra and taking x-ray plates it is possible to study the changes that take place after infection with gonorrhea. Slides were shown to demonstrate the normal urethra, acute anterior and posterior urethritis, prostatitis, prostatic abscess, periurethral abscesses and strictures. Dr. Greenberg put this forward as an additional adjunct in the diagnosis of postgonorrheal complications.

Dr. B. M. Jacobson spoke on "Study in Gout." Three fundamental facts have been generally recognized as actively true in all cases of gout. First, sodium urate crystals are found to be always deposited in the tissues; secondly there is a marked rise of the uric acid in the acute attack and thirdly colchicine is always effective therapeutically. Dr. Jacobson has been working on the problem of why the uric acid is deposited in the tissues. He has studied the changes in the water and mineral metabolism in the typical and acute attacks of gout, and has found that there is always a diuresis of water and sodium chloride resulting in a negative

balance of these substances, and including to a smaller extent, the other minerals. This diuresis may start a few days before the onset of the attack or on the same day as the onset. When the attack is in its full severity, the diuresis stops and compensation takes place rapidly as the patient recovers. This mineral loss is not related to the uric acid secretion or to the fever or drug administered, but it is in proportion to the severity of the attack and is a constant finding.

By the 1930 Folin method of serum uric acid determinations, cases of gout frequently did not have a high uric acid. However, by the new 1934 Folin method, every case has a value above 6 milligrams per hundred cubic centimeters, which is an abnormally high figure. If there is general nitrogen retention, as in nephritis, a high blood uric acid is not significant. Dr. Jacobson also studied the therapeutic effect of purine-free and purine-high diets on the frequency of occurrence of attacks and found practically no difference over a long period of time.

A paper on "A Method for the Prolongation of the Effect of Medication" was presented by Dr. H. L. Naterman. By the use of a purified ester of cholesterol mixed with a small amount of water and added to oil, Dr. Naterman has made a medium in which he can emulsify certain drugs and greatly prolong their period of absorption and therefore their therapeutic effect. First he tried this on phenolsulphone-thalein and found that the absorption was greatly delayed as measured by the slow excretion of the dye. The use of pitressin in emulsion in the treatment of diabetes insipidus has been found to be effective over a much longer time than when the drug is used in water. In this condition, one injection a day is usually enough. Adrenalin in oil has been used in the treatment of asthmatics with encouraging results. Pollen extracts in oil have also been used in certain cases of asthma.

Dr. S. Proger delivered a paper on "Some Effects of Diet Restriction on Patients with Heart Disease." He found that patients on a high caloric intake with severe heart disease and some degree of decompensation after they had reached a level on digitalis were definitely benefited by a reduction of their caloric intake. He put them on 350 calories a day for three days, which amount was then raised to 600 calories and later to 800 calories. By this procedure he reduced the oxygen consumption by 25 per cent, lowered the basal metabolism rate, diminished the weight, lowered the minute pulmonary volume, increased the vital capacity and diminished the diastolic and systolic pressure readings. The pulse rate also slowed down definitely. When the caloric intake was increased and the weight rose, the effect of this treatment was partially lost and the magnitude of the effect was greater when the weight loss took place from a normal level rather than from an obese level.

Dr. H. J. Sternstein spoke on "Quantitative Measurement of Nasal Obstruction." By the use of a simple nasal manometer, he has been able to

measure the resistance offered to a stream of air going through the nasal passages. This resistance can be charted and compared with the normal. Slides were shown of normal cases and those with partial or complete obstruction. This method can be used to advantage in studying the normalcy of the mucous membrane by taking readings before and after shrinkage. It is also of use in measuring the therapeutic effect of various drugs. Dr. Philip Drinker of the Harvard School of Public Health has been using this apparatus to study the filtering ability of the nose. In the normal nose the nasal passages stop from 10-30 per cent of the small dust particles, and Dr. Drinker therefore concluded that it is not an efficient mechanism in protecting against the diseases caused by dust.

The last paper of the evening was on "The Prevention of Anemia in Pregnancy" by Dr. M. B. Strauss. Anemia is common in pregnancy and may be caused by any of the usual factors, but most cases are of the simple hypochromic variety. The incidence is about 25 per cent, and 15 per cent are severe in degree. At birth the baby always has a normal blood hemoglobin and this, therefore, is always a drain on the mother. She should have, during pregnancy, an increased iron intake. By studying 200 pregnant women from the fifth month onwards, at monthly intervals, and giving 100 of them three grains of ferrous sulphate three times per day, and the other half lactose tablets only, he was able to show that this amount of iron was adequate to prevent anemia during pregnancy. Of those who did not take iron, 25 per cent developed anemia. Only 20 of the 200 had good diets. The postpartum percentage of hemoglobin should never be below 70 per cent.

HARVARD MEDICAL SOCIETY

The December 10 meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital with Dr. Henry A. Christian presiding. The medical case was presented by Dr. Lawrence E. Putnam. A forty-four year old housewife entered the hospital five days previously complaining of a "pounding of the heart" of nine hours' duration. She gave a past history of scarlet fever, measles, and mumps in childhood. Ten years ago she experienced the sudden onset of precordial pain and a sensation of pounding of her heart, and was in a hospital for three weeks, during which time the symptoms subsided spontaneously. Since that time she had had frequent attacks similar to the first one, which lasted from a few hours to two weeks. Two years ago she was seen at the Brigham Hospital, at which time physical examination was negative except for a heart rate of 176 beats per minute. Carotid sinus pressure did not slow the rate, but on the second day it caused a fall of the rate to normal. During the month before the present entry she had had frequent attacks, and had been seen in several Boston hospitals in which medication failed to relieve her symptoms.

Nine hours before her admission she was suddenly seized with a severe precordial pain and pounding of her heart. Physical examination on entry was negative except for a heart rate of 183 beats per minute and a blood pressure which could not be determined in the brachial artery. Vagal pressure was ineffective in slowing the rate. An electrocardiogram showed paroxysmal tachycardia of auricular origin. Laboratory and x-ray studies were normal. She was given four cubic centimeters of syrup of ipecac every half hour for three doses which caused vomiting but had no effect on the heart rate. Three quarters of an hour after the last dose, she received one eighth of a grain of morphine and three grains of luminal. One hour later her heart rate was found to be 36 beats per minute, and her blood pressure 90/60. She stated that fifteen minutes after receiving the last medication she experienced the sudden onset of severe precordial pain which radiated to her left arm. There was abrupt cessation of the pounding of her heart. Previous attacks usually terminated in the same manner.

Dr Samuel A. Levine remarked that this was a typical case of paroxysmal auricular tachycardia. Attacks usually last an hour or a few days and it is unusual that they persist for as long as one or two weeks. As a rule there is no cardiac dilatation, although dilatation can occasionally be quite marked. Dr Christian recalled having seen a case with persistent tachycardia lasting eleven days, which resulted in arterial thromboses and subsequent dry gangrene of the arm. The use of ether anesthesia during amputation cured the tachycardia.

Dr Robert Bates presented the surgical case. A fifty-two year old single white male entered the hospital with a history of severe pain in his right arm and hand of twenty-four hours duration. One year ago bilateral ligation of the saphenous veins had been performed for varicose veins. The Hinton test at that time was negative. The blood pressure varied from 170/100 to 100/90. He had been followed in the varicose vein clinic. Physical examination on entry revealed a cadaverous appearing right hand. Pulsations were absent in the ulnar artery but were present in the radial, brachial and supraclavicular arteries, although they were weaker on the right than on the left. There was a thrill and bruit in the right supraclavicular region. The blood pressure on the right was 130/100 and on the left was 100/100. There was decreased sensitivity to pinprick in the right hand. The white blood count was 20,000, the temperature 100 degrees Fahrenheit. Electrocardiography and fluoroscopy studies of the heart were negative. There were no cervical ribs. He received passive vascular exercise with a leg pump which led to decrease in pain and return of warmth to the hand. No diagnosis was made although it was felt that a partial thrombosis of the right subclavian artery might account for the observed signs and symptoms.

Dr Soma Weiss of the Boston City Hospital spoke on "Types of Syncope: Their Mechanism and

Treatment. In studies of hypertension and observation of vasodepressor and carotid sinus reflexes, certain patients were observed who were subject to attacks of fainting. It was thought that the carotid sinus reflexes might be the cause of the syncope, and this possibility was investigated. Subsequently the studies were extended to other types of syncope in an attempt to explain the mechanism of their occurrence. Syncope is a syndrome in which an intimate relationship exists between the central nervous system, the viscera and particularly the circulatory system.

Syncope may be defined as an acute transient state of the body in which there is a temporary partial or complete cessation of locomotion, consciousness and occasionally of respiratory and circulatory activity. In spite of the fact that many cases of syncope present an identical clinical picture the underlying mechanism and treatment is quite different in different cases. Dr Weiss classified syncope according to the mechanism of production.

- 1 Vasovagal syncope. The "common faint"
- 2 Carotid sinus reflex syncope due to hyperactivity of the reflex.
- 3 Vagovagal syncope. Adams-Stokes syndrome of reflex origin.
- 4 Pleural shock syncope. Many cases so diagnosed have been caused by an air embolus but syncope actually does occur occasionally from traumatic irritation of the pleura.
- 5 Pericardial shock syncope. Similar to pleural shock.
- 6 Peritoneal shock syncope. There is no evidence for the existence of a specific form of shock from peritoneal irritation. Syncope occurring during abdominal paracentesis is probably vasovagal in mechanism.
- 7 Syncope with central vasomotor stimulation.
- 8 Adams-Stokes syncope of nonreflex origin, from complete heart block of sudden onset.
- 9 Syncope from sudden increase in heart rate. This may be due either to a reflex or to a decrease in cardiac output, or to both.
- 10 Syncope with attacks of angina pectoris. This may be due to a reflex.
- 11 Syncope with congestive failure of the circulation.
- 12 Syncope with postural hypotension.
- 13 Syncope with engorgement of the central nervous system.
- 14 Syncope with pulmonary circulatory engorgement.
- 15 Syncope with a dissecting aneurysm. A dissecting aneurysm is frequently characterized by a tear at the root of the aorta, in which area the depressor nerve runs. Syncope in these cases may be due to depressor nerve stimulation.
- 16 Nothnagel's syndrome "vasomotor angina." This may be related to the carotid sinus reflex group.
- 17 Gowers syndrome. This corresponds closely to the cerebral type of carotid sinus reflex.

The *vasovagal type of syncope* is quite variant in its manifestations. It may be mistakenly diagnosed as epilepsy, or even as angina pectoris. Dr Weiss and his associates found that by administering sodium nitrite to normal individuals it was possible to induce all the symptoms of this type of syncope. The normal individual without medication shows certain changes in the cardiocirculatory system upon assuming the erect posture. There is a drop in the systolic blood pressure and a rise in the diastolic pressure, with resultant lowering of the pulse pressure. The heart rate is moderately accelerated. If a subject is given sodium nitrite and then is caused to assume the erect position, there is a progressive drop in both systolic and diastolic blood pressures, and an increase in heart rate. Pallor ensues, and syncope may occur. As soon as the horizontal position is reassumed, the heart rate and blood pressures return to normal.

If patients subject to vasovagal syncope are placed on a tilting table and tilted toward the erect posture there is an immediate decrease in pulse pressure, and a marked increase in heart rate. There is a temporary rise in the venous pressure in the foot vein, followed by a progressive fall. The blood flow through the hand may be normal for a period but preceding the syncope there is a rapid progressive fall. On resumption of the horizontal position, there is a prompt return of the above enumerated factors to normal levels.

Patients suffering a chronic tendency to this condition are benefited by improved posture and by adequate physical exercise.

Carotid sinus syncope must be considered as being due to one of two different mechanisms: (1) to cerebral ischemia, or (2) to a reflex depression of certain central nervous system centers.

Thus there may be three different types of carotid sinus syncope:

1 Vagal, characterized by (a) cardiac asystole, (b) cerebral anoxemia, (c) being abolished by atropin or adrenalin.

2 Depressor, characterized by (a) fall in arterial pressure, (b) cerebral anoxemia, (c) being abolished by adrenalin (atropin has no effect).

3 Combined, characterized by (a) normal heart rate and blood pressure, (b) normal total cerebral blood flow, (c) not being abolished by drugs.

There may be various combinations of these three types.

Carotid sinus stimulation in a normal individual will produce only a slight slowing of the heart rate. Novocain infiltration of the region of the sinus will abolish the slowing observed in normal individuals, and also the syncope observed in patients with hyperactive reflexes.

The dizziness and fainting observed in some individuals after receiving digitals are due to an idiosyncrasy and great sensitivity of the sinus reflex to this drug.

Determinations of the oxygen tension in the blood

of the carotid and internal jugular arteries have shown that there is no essential difference between the levels found in a normal individual and in a patient with a purely reflex type of carotid syncope. In cardiac syncope, on the other hand, there is a definite anoxic stimulus to the nerve endings of the sinus.

In ten patients with unilateral hypersensitivity of the carotid sinus reflex, the carotid sinus nerve was severed, with relief of symptoms, and without ill effects except in one case in which there was transient high blood pressure and auricular fibrillation.

Vagovagal syncope is a purely vagal reflex. A powerful afferent impulse is carried up the nerve to the vagus center and a resultant powerful impulse is carried down the same nerve, with inhibition of the conduction of the excitatory heart impulse, and at times transient heart block. Dr Weiss has studied four cases of this type: two in which esophageal diverticuli produced pressure on the vagus and initiated the reflex, one in which a metastatic carcinoma of the thorax caused infiltration of the vagus nerve, and a fourth in which irritation of nerves in the throat produced long pauses in the heart rate. Administration of adrenalin or ephedrin will lessen or abolish these symptoms, although the transient heart block still persists and is unaffected by the medication. Oral or subcutaneous administration of atropin compounds, or novocain infiltration of the vagus completely abolishes these reflexes and prevents the production of the heart block. Small amounts of tincture of belladonna by mouth usually control these cases well. The carotid sinus reflex was found to be normal in these individuals.

The onset of extremely rapid heart rates due either to paroxysmal or to ventricular tachycardia frequently precipitates an attack of syncope. The cardiac output in these cases is markedly diminished, and the decreased blood supply to the brain results in cerebral anoxemia and fainting.

In summary, Dr Weiss again emphasized the fact that syncope is a symptom and not a definite entity. From a known mechanism in the periphery of the body various types of syncope can be produced which superficially appear identical, but which are in actuality quite dissimilar. The mode of action of these mechanisms in producing syncope depends upon (1) primary ischemia of the brain, (2) primary inhibition of central nervous system centers, (3) a combination of these two factors.

During the discussion Dr Weiss stated that the carotid sinus reflex is usually hypersensitive bilaterally, if found to be so on one side, but that cases of unilateral hypersensitivity are sometimes encountered. The reflex is more easily elicited with the patient in the erect rather than in the horizontal position. The frequent variations in the level of the sinns in the neck often make it difficult to locate. If symptoms similar to those complained

of by the patient can be produced by pressure on the carotid sinus. It is logical to assume that hypersensitivity of the reflex is responsible for these symptoms. Hypersensitivity without syncope exists but most normal individuals fail to show slowing of cardiac rhythm or show only very slight decrease even though extreme pressure is applied to the sinus. Reports of carotid body tumors have not given any history of coincident syncope, although aneurysmal dilatation of the carotid sinus may cause syncope at times.

DOCTOR WESSELHOEFT ADDRESSES MEDICAL GROUPS

MEETING OF THE ARLINGTON AND BELMONT CLUBS AT THE RING SANATORIUM

At a meeting of the Arlington and Belmont Doctors Clubs which was held on Tuesday evening January 14 at the Ring Sanatorium and Hospital in Arlington Heights Dr Conrad Wesselhoeft, Chief of the Haynes Memorial Contagious Hospital at Brighton and Associate in Communicable Diseases at the Harvard Medical School addressed a group of nearly 100 physicians.

Dr Edwin P Stickney of Arlington, voiced the sentiment of those present in an eloquent tribute to the life and work of the late Dr Arthur H. Ring and to the institution which Dr Ring and his wife, Dr Barbara T. Ring developed to its present status.

Dr Wesselhoeft spoke on some of the problems in the diagnosis and treatment of scarlet fever. He said that the disease has become generally milder in the last fifty years. Eleven years ago the cause of scarlet fever was discovered, and we now have effective means of preventing this disease as well as an antitoxin which, if given early alleviates the sore throat and fever and blanches the rash. Unfortunately the administration of this antitoxin is sometimes attended with severe reactions. Consequently it is not generally given in mild cases. Every attempt is being made to rid this antitoxin of these unfavorable reactions. The greatest danger of scarlet fever now lies in the complications which may occur. While early serum treatment may to some extent lower the frequency of these complications, it cannot be relied upon to do this. Once these complications arise the serum is useless and the physician must turn to other measures often of a surgical character.

Dr Wesselhoeft spoke of the Dick patent which controls the immunizing agent as well as the antitoxin. In his opinion there was no excuse for the continuation of this patent. He said that if there should be the same progress in the treatment of scarlet fever in the next fifty years as that which followed the invention of the telephone fifty years ago and as many patents were to be taken out as have been taken out on the telephone, the situation in medicine would be unthinkable. He visualized doctors guarding their secret discoveries for patenting purposes instead of sharing with one another each forward step in medicine according to the time-

hallowed custom and ideals of the medical profession. Attention was called to the recent criticism of the Dick patent by the Public Health Council of the League of Nations. He said that the generous support of medical research by the laity demands that physicians should turn over their discoveries for the benefit of all without those restrictions entailed by a legalized commercial monopoly.

Dr Wesselhoeft's paper was discussed by Dr Charles A. Atwood, Dr Edwin P. Stickney, Dr Edwin H. Place, Dr James M. Baty, Dr James H. Townsend and others.

Dr Hosea W. McAtee, Medical Director of the Ring Sanatorium and Hospital, presided.

WORCESTER NORTH DISTRICT MEDICAL SOCIETY

The quarterly meeting was held at the Leominster Hospital January 23. The president, Dr George P. Norton, called the meeting to order at 4:20 and after the reading of the records and other preliminary measures, bills before the Legislature were considered.

Several members of the Legislature from the district, comprising an area from Ayer to Athol have been invited to attend the meeting. Among them were Senator Edward H. Nutting of Leominster and Representatives Heary A. Estabrook of Fitchburg, and Fred A. Blake of Gardner.

Dr Alexander S. Begg, Secretary of the Massachusetts Medical Society discussed the relation of the Society to legislation. He reported that the Society was opposed to Senate 24 which would abolish the several boards of all state institutions and transfer to the Governor and the Executive Council all the powers and duties now resting in the hands of the many boards supervising them. It was felt that this bill savored too much of politics. In this contention he was supported by the others present.

He explained that the chief medical function of the Legislative Committee of the State Society is to inform the legislators of the attitude of the doctors respecting bills under consideration especially those for the public interest. There is a single standard governing the practice of medicine in Massachusetts and that standard is a proper and sufficient education. Certain cults claim that special legislation to control medical education is not necessary but it was explained that the Society is not in agreement with them. There have been more than sixty unnecessary fatalities in the state due to cult practice.

House 34 is designed to raise the qualifications of those who apply for registration as physicians and is endorsed by the State Society. Under the proposed bill only graduates from approved schools may be qualified to practice medicine.

The bill to regulate magnetic healers is opposed because the State Society feels that a single standard is effective.

Opposition was also expressed to the Anti-Vaccination bill and the act for a special board to regulate chiropractors. The State Society has reached

no decision on the bill requiring physicians to register annually, and pay a fee of \$2 00

Representative Estabrook said that it was important to know the doctors and learn their viewpoint. He said that the bills in which the profession is especially interested may be classified as follows: education, public health and compensation. He said that House 34, which is designed to provide one standard for all who practice medicine, would fail because of one definite defect.

"Despite our boasts of educational standards," he said, "Massachusetts, in contrast with every other state, has no standards in medical education."

Such a proposed change as that contained in this bill would act in conformity with the plan of the board of regents in New York, where a candidate for registration in medicine is first obliged to pass an examination of standardized educational requirements. After passing this successfully, he can take the examination for registration in medicine. Such a plan in Massachusetts would promote reciprocity between states. Under present conditions, Massachusetts has been denied recognition throughout the country.

In the absence of these educational standards, students from other states come to Massachusetts and may pass the state registration board after failing elsewhere.

They are then allowed to practice in Massachusetts, thereby giving the state a large number of undesirable practitioners. If there were an amendment to the bill providing for a board of regents it would have a chance of passing, but doubt was expressed of its endorsement, in its present form, by the Legislature.

Representative Estabrook has worked for eight years to have such legislation as this enacted, but has been unable to bring it about.

Senator Nutting said that doctors should become interested in legislation relating to medicine and in form the legislators of their desires, for in no other way can the layman arrive at a satisfactory decision.

Representative Blake said that legislation should not be treated lightly. He felt that the legislators are trying to do the best they can for the public and if an occasional slip is made, it is because they are not informed.

Other business was discussed. A vote of thanks was given to the speakers. The fifty-five doctors present voted that the meeting had been both interesting and enlightening.

The Women's Guild of the Leominster Hospital served a delicious turkey dinner.

FRANCIS M. McMURREAY, M.D., *Secretary*

BOSTON TUBERCULOSIS ASSOCIATION

The Annual Meeting of the Boston Tuberculosis Association was held at the Sheltered Shop, 122 A Newbury Street, Boston, Friday, January 24, 1936, at 4 P.M. The following officers were re-elected: Dr. John B. Hawes, 2d, President, Mr. George S.

Mumford, Treasurer, Dr. James J. Minot, Vice-President, Mrs. Reginald Heber White, Clerk.

Dr. Hawes, in his annual report, which is the sixteenth he has given before this Association, summarized the salient and important features of the year's work, particularly that of the Prendergast Preventorium and the Sheltered Workshop. By means of a striking graph he showed the gratifying and steady increase in the sales of products made by the expatients at the Workshop. He commented on the educational work still being carried on since its beginning in 1927 among the Negroes of the South End district and upon the steady progress being made in the work with the Chinese. In concluding he emphasized as he has many times before that the Boston Tuberculosis Association was not primarily interested in dollars and cents or any figures and statistics or any gains or losses of weight but it is vitally interested in human beings who have tuberculosis and those who are threatened with it, in order that their lives may be made happier and better by this Association.

The annual address which was most illuminating was given by Dr. Cleaveland Floyd, Physician-in-Chief of the Boston Health Department Tuberculosis Clinics and member of the Executive Board of the Boston Tuberculosis Association. He commented on the drop in the tuberculosis death rate from 1647 to 555 in the past twenty-five years, and on the improved facilities for the examination for diagnosis and the care of patients both at home and in the sanatoria. He stated that even today there is not a sufficient number of beds for tuberculous patients in Boston. He also stated that at present the common cold contracted by tuberculous patients makes it one of the greatest factors in causing them to break down a second time.

Dr. Elliott P. Joslin, an abstract of whose address appears below, spoke on "The Prendergast Preventorium Boarding School for Diabetics."

ABSTRACT OF DR. JOSLIN'S ADDRESS

The Boston Tuberculosis Association started something this year when it inaugurated the first Diabetic Boarding School in the country and, so far as I know, in the world. It is true this boarding school is chiefly for underprivileged children, but the significant point is that it is started and that the idea is sound and sure to spread to other communities.

For some years there have been diabetic camps in Massachusetts and, through the efforts of the Universalists and other friends, nearly 100 diabetic girls were cared for at the Clara Barton Homestead in North Oxford last summer. Thanks to the assistance of the Prendergast Preventorium and the ladies of the Unitarian Church, the Preventorium became available for diabetic children this last year and thirty boys had a good vacation thereby. In the autumn it seemed a shame to send them home and during this winter ten or more have been kept at

the Preventorium and allowed to go to school. Diabetic children are prone to tuberculosis and consequently it is especially appropriate for this association to be interested in them.

The arrangements for these children are quite ideal. They have good diabetic care there are enough of them so that they are not distinctive thanks to the School Committee of Boston they are provided with facilities for education and while gaining this they are securing diabetic training which will last them for years.

Diabetes for the Diabetics I firmly believe that the prevention and care of diabetes should rest upon the families of diabetics and upon the diabetics themselves. The number of diabetics who are very poor or very rich is small. There are I suppose half a million diabetics in the country and 15,000 in the state of Massachusetts but the great bulk of them are perfectly capable of looking out for themselves and one another. To the family of a diabetic one should look for the prevention of the disease among other members. This is accomplished first, by emphasizing the importance of obesity in middle life in favoring the onset of the disease and secondly by the simple rule that one diabetic should not marry another diabetic and thus transmit the disease to the children. In general it is better for a diabetic not to marry into another diabetic family.

Provision for the care and treatment of poor diabetics should be undertaken by diabetics. The more diabetics a patient in good circumstances can make it easy for his own physician or for hospitals and clinics to treat, the better that patient will be treated himself.

Improvement in treatment is what is needed all along the line in diabetes. In general we do not spend large sums of money for hospital diabetic beds but instead moderate sums of money so that the occupants of these beds can be treated better and more expeditiously. Formerly a diabetic would occupy a bed for a month. Now treatment is carried out in ten days or a week, and three or four times as many patients get the benefit for the same cost. With more careful planning greater attention to the details of the education of the patient and last of all, with the help of the new and safer insulin hospital treatment can be speeded up still more.

Arrangements must be provided so that private physicians can secure laboratory facilities as easily as these are obtained by hospital physicians. I believe that a donation of \$1,000 annually to each of a dozen or more hospitals in this State for the promotion of its diabetic work, particularly for making available more generally the facilities of its laboratory would be of infinitely more value than that same sum if expended on the board of a few patients in these same hospitals. We need better facilities and it is true that we doctors need more brains to utilize the treatment already at hand.

At the Prendergast Preventorium fortunately the facilities are already available for good medical treatment of the children. A laboratory was erect-

ed last year and this is also gone on in diabetic treatment. The organization of your Prendergast Preventorium Mr. President, is splendid and so far as I can see your chief need and the diabetic's chief need is for funds so that you can fill your beds to capacity with diabetic children at \$10 a week.

I appreciate the privilege of being able to say a word at this time for the Clara Barton Homestead Camp at North Oxford. That camp however not only needs money this year for the board of children but it requires an artisan well a kitchen with modern refrigeration, and a dining room.

The cost of the diabetic camp and boarding school at the Prendergast Preventorium and the Clara Barton Homestead Camp last year reached about \$8,000. This year I certainly hope that more funds will be provided so that both of these camps can be made available to an even greater number of children. For equipment and children twice this sum could be advantageously expended. I hope you all realize that \$10 will do far more than provide board for a child for a week because there are many children whose parents can pay one-half or one-third of this sum, provided the balance is made up. Thus far I know of exactly \$300 available for providing 150 diabetic children a vacation in the camp at the Prendergast Preventorium or at the Clara Barton Homestead Camp but I am not going to worry about the balance needed because there are 15,000 diabetics in the state of Massachusetts and it is for the interest of each one to help himself or herself by seeing that this opportunity for diabetic children to get a vacation and good treatment is afforded. Every diabetic who is able to do anything for another diabetic should do so. It is broad cast on the waters and is sure to return many many fold.

Anyone wishing to give money for camps for diabetic children I hope will specify that it is for that purpose and send it either to the Boston Tuberculosis Association for its work at the Prendergast Preventorium or to the Women's National Missionary Association of the Universalist Church at 16 Beacon Street for the Clara Barton Homestead Diabetic camp. Should any funds be sent to me I will agree personally to be responsible for the expenditure in these two institutions and render an account of the same.

THE NEW ENGLAND PHYSICAL THERAPY SOCIETY

The regular meeting of the New England Physical Therapy Society was held at the Hotel Kenmore, Wednesday evening January 15 1936. The council met at six o'clock.

The scientific meeting was held following dinner. Dr. Charles W. McClure president of the society presided. The first part of the program was devoted to a report by Dr. DeWitt G. Wilcox of Newton and Dr. William D. McFee of Boston on evaluation and progress in the field of short wave therapy. Dr. Wilcox stated that he had had several cases of pylorospasm probably partially on a neurotic basis which

had responded well to short wave therapy after other methods of treatment had failed. He also mentioned three cases of so-called "irritable bladder" (pain and frequency were the two most striking symptoms) which had responded well to treatment. As far as head colds and sinusitis are concerned, Dr Wilcox believes that he has obtained good results with this form of treatment. Dr McFee also said that he had obtained good results in frontal sinusitis and described a new electrode he is using in treatment of the prostate gland. In his opinion short wave therapy is a little better than diathermy in many cases, although it will not entirely displace it. Where bone structure is concerned there is definitely more penetration with the short wave.

The chief speakers of the evening were Dr George Rice and Dr Nathan L. Fineberg, who spoke on the treatment of hyperesthetic rhinitis and the modern treatment of the common cold. Dr Rice first showed slides demonstrating the anatomy of the nose and the paranasal sinuses. He then discussed the etiology of hyperesthetic rhinitis, with polyposis as a frequent complication of this disease. If the irritable areas are not too extensive, early cauterization helps. The condition is usually allergic in background, but this may not always be true. In the allergic state eosinophils are usually present in the nasal secretions. If the nasal mucosa is desensitized in these patients, usually there is clearing up of the associated asthma. The condition is either periodic (seasonal) or chronic. In seasonal types careful search for the causative agent is important. As for the treatment of the nose, there have been three types of procedure: ionization methods, cauterization with full strength phenol, and diathermy. Preliminary cocaine anesthesia is necessary and correction of underlying nasal deformities, if any, must be effected as a preliminary measure. Dr Fineberg discussed ionization methods in a little more detail, especially as developed by Warwick, and reported good results with this form of treatment in patients with marked hay fever and asthma and has also obtained satisfactory results with ionization in atrophic rhinitis and ozena. The most striking successes have been obtained in seasonal hay fever after it has developed, he also feels that there is a good chance of clearing up associated asthma, if that is present. Results have not been good with asthma unrelated to hyperesthesia in the nose. The speaker also emphasized the importance of correcting underlying deformities in the nose.

In discussing atrophic rhinitis, Dr Rice indicated that he had obtained good results by the use of ultraviolet light, and proceeded to discuss the modern treatment of the common cold. He stressed the importance of general hygiene and good physical condition, and mentioned local and general methods of treatment of the cold itself. Rest in bed, at least for the first twenty-four hours, hot drinks, and foot baths are important adjuncts to treatment. He has used sodium iodide subcutaneously and also

nonspecific protein injections. Two grain doses of ammoniated quinine are also recommended, and ultraviolet light and radiotherapy often help. After the acute stage is over, argyrol packs in the nose relieve ethmoiditis and complications.

In discussing this paper, Dr Fineberg pointed out the importance of attending to the patient's general condition, both in treatment and prevention.

A general discussion followed and Dr McClure closed the meeting with a few words on the importance of diet, proper nutrition, and food elements in health and disease.

PHYSICIANS' ART SOCIETY

At a meeting held December 10, 1935, the following officers were elected:

President Dr Frederic J. Cotton

Vice-President Dr Fritz B. Talbot

Secretary-Treasurer Mr James F. Ballard

Executive Committee Dr Eli C. Romberg (3 years), Dr Lewis W. Hill (2 years), Dr Somers H. Sturgis (1 year)

The Society has been very fortunate in enlisting the interest of Doll and Richards, who have offered the free use of their galleries for the spring exhibition. This will be held from April 27-May 9 and details will be published later. It is felt that the interest of such a prominent gallery does much to stimulate the Society, and it is urged that all members prepare new material, as nothing will be accepted that has been shown at any of the previous exhibitions. In addition to paintings, drawings and sculpture, other creative specimens of handicraft are eligible. Photographs will not be accepted. There is no limit to the number of subjects which can be sent by any one man, but a professional jury will select a limited number, and supervise their hanging.

All physicians who are interested in art and craftsmanship are cordially invited to join the Society. Application should be made to Mr Ballard at the Boston Medical Library.

WILLIAM HARVEY SOCIETY

The William Harvey Society met at the Beth Israel Hospital, January 10, 1936, with Dr W. F. Stearns presiding. Dr H. Houston Merritt, associate in neurology at Harvard Medical School, read the paper of the evening on "Syphilis of the Nervous System."

The important aspect of a syphilitic infection is the outcome of the disease fifteen or twenty years after the primary lesion, when the central nervous system and cardiovascular involvement overshadow the relatively unimportant first and second stages of the disease.

Bruusgaard's study of 473 cases of untreated syphilis some forty years after the detection of the disease showed that twenty-two per cent had died of causes other than syphilis, twenty-eight per cent

had no clinical evidence of syphilis but had negative serology. Fourteen per cent had positive serology but no symptoms or clinical manifestations of the disease. Nine and five-tenths per cent suffered from neurosyphilis, twelve and eight-tenths per cent from cardiac syphilis and thirteen and five-tenths per cent from syphilis of the skin and bones.

In contrast to these figures Dr Merritt cited the results obtained by Moore from adequate therapy

markedly abnormal fluid means that serious neurosyphilis will most certainly develop unless proper therapy is given.

Acute syphilitic meningitis is not caused by meningococci as was formerly believed by some workers but is due to spirochetal invasion of the meninges. Sixty-four per cent of cases occur during the first year of infection and there is a subsequent steady fall in incidence. The blood Wassermann

Type of syphilis		Probable outcome expressed in approximate per cent		
Original diagnosis	Ultimate outcome	Untreated	Inadequately treated	Thoroughly treated
Early syphilis	Serious late syphilis	25	35-40	5-10
	Benign late syphilis	15	16	5
	Latent syphilis	30	30	5
	"Cure"	30	15-20	80-85

Consideration of these comparative figures clearly shows the value of early and thorough therapy of every case of syphilis.

Central nervous system involvement due to syphilis is seen more frequently in males than in females, and the white race is much more prone to develop lesions in this region than is the Negro race. Some investigators believe that ninety per cent of white males contracting syphilis develop central nervous system involvement to some degree. The true incidence of central nervous system involvement in the white male is probably not so high as indicated by these figures, but nevertheless is strikingly common.

Syphilitic involvement of the central nervous system may be classified in the order of increasing severity:

1. Asymptomatic
2. Meningeal
3. Vascular
4. Gumma
5. Tabes Dorsalis
6. Dementia Paralytica

Abnormalities in the spinal fluid are of great importance diagnostically and are an indication of the efficacy of therapy. Although thirty-five per cent of individuals with syphilis exhibit abnormal spinal fluid findings in the first thirteen to eighteen months after infection those with positive findings three or more years after infection are the cases which will develop serious nervous system involvement if not treated properly. It is in this and earlier stages that therapy is most effective and can be expected to prevent the development of serious parenchymatous involvement. Dr Merritt advocates a spinal puncture and study of the spinal fluid in all cases of early syphilis before treatment is discontinued, and as soon as the diagnosis is made in the cases of late syphilis. A normal spinal fluid two years after infection is almost certain indication that there will be no nervous system involvement at a later date. A

in a series of seventy-four cases was negative in thirty-five per cent. Hinton determinations are more accurate and this percentage of negative results would be much lower for this test. A large percentage of the cases of syphilitic meningitis develop an acute hydrocephalus and practically all show an elevation of spinal fluid pressure. Signs of meningeal irritation and choked discs are also common manifestations. Paralysis of the cranial nerves occur in the basilar type the eighth seventh and third being most frequently involved. Pathologically acute syphilitic meningitis is characterized by small round cell infiltrations of the meninges and the blood vessels in the superficial layers of the brain.

Vascular neurosyphilis may occur early or many years after the primary lesion and a large percentage of cases may have a negative blood Wassermann. A smaller number of cases also have negative spinal fluid serology. The symptoms are those of a focal cerebral lesion i.e., hemiplegia, hemianopia, aphasia, etc. The differential diagnosis of a cerebral thrombosis due to arteriosclerosis and that due to infectious endarteritis may be very difficult, but if symptoms indicative of such an accident occur in a comparatively young individual with a normal blood pressure syphilis should be seriously considered and the spinal fluid examined to exclude it.

Gummatous of the central nervous system are extremely rare, and therefore of little clinical importance. When present surgical removal is usually necessary.

Involvement of the spinal cord by syphilis usually takes the form of a meningomyelitis, vascular thrombosis, chronic anterior poliomyelitis or tabes dorsalis. Except for tabes dorsalis these manifestations are rather rare.

Tabes dorsalis is characterized by paresthesias, shooting pains, disturbance of gait, vision and sphincter control and the so-called "tabetic crises." The Romberg sign is frequently present, the deep reflexes are absent and position sense is lost in the

feet The true Argyll Robertson pupil is found in more than fifty per cent of the cases

The Argyll Robertson pupil is almost pathognomonic of central nervous system syphilis and may be defined as having the following characteristics

1 A retina which is sensitive to light (An intact retina and visual pathway)

2 The pupil is miotic (Due to paralysis of the sympathetic innervation of the iris)

3 The pupil maintains a constant size regardless of the amount of light admitted to the eye (Due to paralysis of the light reflex fibers)

4 Active accommodation of the pupil for near objects is maintained (Showing an intact pathway from the cortex to the third nucleus, and from the third nucleus to the ciliary muscles of the eye)

5 Imperfect dilatation following instillation of atropine and absence of dilatation when painful stimuli are applied to the skin. (Characteristic of paralysis of the sympathetic innervation of the eye)

Dr Merritt discussed the anatomical location of the lesion which would produce these symptoms, and stated that the Argyll Robertson pupil indicates parenchymatous involvement of the central nervous system, and although not absolutely diagnostic of any one form of neurosyphilis, is suggestive of involvement of the tabetic or dementia paralytic type

Dementia paralytica is the most severe of the various manifestations of central nervous system syphilis. Change of personality, mental deterioration, hallucinations, euphoria, speech and writing defects, convulsions, reflex disturbances, and Argyll Robertson pupils in combination are pathognomonic of paresis

Pathologically, paresis is characterized by a generalized infiltration of the meninges, blood vessels and occasionally the cortical substance with plasma cells, and degenerative changes in the nerve cells. Deposits of iron pigment in the microglia and in the walls of the blood vessels in the brain, as revealed by special iron stains, have come to be regarded as diagnostic of paresis. Spirochetes can be demonstrated in the cortical tissues

Spirochetal invasion of cortical matter is probably not the only cause of the lesions observed in paresis. The blood vessel changes characteristic of paresis and the subsequent decrease in blood supply probably play a large part in the degenerative changes

Therapy of central nervous system syphilis with various arsenical preparations has proved of great benefit. Arsphenamine is of greatest value in the treatment of the early stages of syphilis, but has been superseded by the less toxic neoarsphenamine in the later stages of the disease. Tryparsamide is almost specific for central nervous system syphilis, but is ineffectual in treating other luetic manifestations

Fever, artificially induced by means of diathermy or malaria has been the greatest recent advance in

the treatment of neurosyphilis. The malaria method of hyperthermia consists in the infection of the patient by intravenous administration of blood from an individual with malaria, and allowing the patient to experience ten to fifteen attacks of chills and fever. Cure of the malaria is easily achieved by the oral administration of quinine. Tryparsamide therapy should be instituted immediately after completion of the fever treatment. In dementia paralytica, clinical cures occur in percentages varying between twenty and thirty six per cent of the cases so treated, and partial relief is obtained in fourteen to fifty per cent of cases. Modern methods of therapy have changed central nervous system syphilis from a disease with a hopeless prognosis to a disease with a favorable outlook.

HAMPDEN DISTRICT MEDICAL SOCIETY

The Winter Meeting was held at the Springfield Academy of Medicine, 20 Maple Street, Springfield, on Tuesday, January 28, 1936, at 4 15 P M. Dr Theodore S. Bacon, President, was in the Chair. About 120 members attended.

The Secretary read a letter from Dr Charles G. Miles of Brockton, a member of the Legislature, regarding a bill to be introduced affording better protection to physicians called on for services in connection with automobile accident cases and appealing for funds for the purpose of giving radio addresses. The Society voted to appropriate the sum of twenty five dollars toward this purpose. An invitation to the New England States Regional Conference on Birth Control was read.

The paper of the afternoon was by Dr John Homans of the Peter Bent Brigham Hospital and the Harvard Medical School, Boston, on the subject of "Thrombosis in Veins as a Complication of Medical and Surgical Diseases." Dr Homans discussed the causes and manifestations of such thrombosis, especially postoperative and posttraumatic, the possible sequelae, such as pulmonary emboli, and the methods of prophylaxis and treatment. The paper was discussed by several members and questions answered. A rising vote of thanks was given Dr Homans for his very interesting and practical presentation, and a buffet supper was served.

ANDREW PETERS, M D, Reporter

ROBERT BRECK BRIGHAM HOSPITAL CLINIC

Osteoarthritis was the subject of a clinic held at the Robert Breck Brigham Hospital, Wednesday, January 29, 1936. Two cases were presented. The first, a Scotch baker, aged fifty seven, had been troubled for ten years with pain in both knees. No other joints gave symptoms. During the past year he had been forced to give up two jobs because of the great pain he experienced when standing for any length of time.

The patient was short, stocky, muscular, and weighed 160 pounds. The positive physical findings were absence of teeth, round shoulders, large

abdomen, prominent knee joints, slight bowing of the legs and flat feet. All laboratory tests including the usual blood and urine studies Hinton test, gonorrheal complement fixation, blood uric acid, prostatic smear and basal metabolic rate were within normal limits. X-rays revealed osteoarthritic changes in the hands, knees, feet, spine and pelvis with marked spur formation and well-defined calcareous deposits, particularly in relation to tendinous attachments.

The second patient, a woman aged fifty-one had been troubled with increasing disability of the hip joints for twelve years. On admission she could walk with a cane. Other joints were symptom free except the knees, to which pain was referred from the hips.

She was a short, stout woman weighing 145 pounds. The striking physical finding was the great limitation of motion in the hips certainly less than half the normal range. Laboratory data were not unusual although the sedimentation rate was 47 mm./hr. (Westergren). X-rays showed great changes in the hip joints with mushrooming of the femoral head, shortening of the neck of the femur narrowing of the joint space, shelving of the acetabulum and generalized atrophy.

In the discussion it was suggested that certain similarities existed in the two patients, i.e., they were over fifty years of age, the arthritic symptoms had been gradually developing over a ten year period, the larger joints were involved, both were overweight, they ran an afebrile course, blood counts and hemoglobin were normal, and improvement was achieved with supervised bedrest with graded postural exercises. The possibility of a developmental anatomic variation with respect to the hip joints in the second patient was mentioned as possibly contributing to the unusual change as demonstrated by x-ray.

The conclusion was reached in each case that it was doubtful if osteoarthritis could account for all the pathology demonstrated by x-ray. The element of wear and tear on large weight-bearing joints together with long repeated intra-articular trauma gave sufficient grounds however for grouping these cases in that category which includes degenerative hypertrophy or osteoarthritis.

With protection to the joints involved the knees in one case and the hips in the other and graded weight bearing exercises it is to be expected that both patients will again take up their usual work within a three to six months period.

ESSEX NORTH DISTRICT MEDICAL SOCIETY

The semi-annual meeting of the Essex North District Medical Society was held at the Riverside Tavern Wednesday January 8 1936. Dinner was served at 12:30 P. M. after which the meeting was turned over to Dr. Charles E. Mongan of Somerville, President of the Massachusetts Medical Society by Dr. Warren of Amesbury, President of the District Society.

Dr. Mongan requested the cooperation of the Fellows in the Society and touched briefly on the service the Society offers to its Fellows.

Dr. W. Reid Morrison of Boston, Chairman of the Committee on Arrangements for the Annual Meeting was then introduced by Dr. Mongan. Dr. Morrison outlined the plans for the meeting to be held in Springfield June 8, 9 and 10 and urged every member to attend.

Dr. Mongan next presented Dr. Alexander S. Begg, Secretary of the State Society and Dean of the Boston University School of Medicine. Dr. Begg asked that all Fellows get behind the Society in support of the legislation for elevation of the standards for admission to practice in Massachusetts. He forcefully emphasized the point that Massachusetts has the lowest standard of any state in the Union for the registration of physicians and the only state that does not give the Board of Registration power to discriminate against inferior medical schools. The Massachusetts Medical Society has been trying for several years to remedy this condition and it was suggested that if the Legislature continued to refuse changes the fight would be taken to the people.

Dr. Begg also discussed the proposed law of re-registration of physicians estimating that, if this law were put into effect, approximately one thousand illegal physicians would probably be discovered whom the Board of Registration in Medicine is now unable to locate.

Dr. Channing Frothingham of Boston, Vice-President of the Massachusetts Medical Society and Chairman of the Subcommittee on Public Health and Practitioner asked that immunization work and other public health measures be more actively carried on by private practitioners. This brought out the fact that the State Department of Public Health does not wish to continue this work after the people have been educated to go to their family physicians for this service.

Dr. Michael A. Tighe of Lowell, Chairman of the Subcommittee on Social Legislation and Insurance, was introduced by Dr. Mongan. Dr. Tighe reminded the Fellows that the House of Delegates of the American Medical Association in February 1935 went on record as opposed to Compulsory Sickness Insurance, because of the interposition of politics between the medical practitioner and the public. He called attention to the fact that the Public Relations Committee and Council had endorsed this stand and had resolved that they should endeavor to educate the public regarding the evils incident to the workings of Compulsory Sickness Insurance. Evidence of cooperation of the press was shown by Dr. Tighe, and the endorsement by the press of the attitude of the Massachusetts Medical Society in this matter.

The business meeting of the District Society was opened by Dr. Warren, the president. The minutes in abstract were read by the Secretary. The resolution on the death of Dr. Edward F. Lawlor of Lawrence was read and voted to be spread on the records and a copy sent to his family. The com-

mittee on the resolutions on the death of Dr John Massé of Lawrence was not ready to report.

Dr Burnham of Lawrence called attention to the fact that the District Society, in its membership records the name of every eligible physician in the District. Twenty-five per cent of these are not Fellows of the American Medical Association as compared with sixty per cent who are not Fellows in the state.

Dr Burnham urged support of the Legislature on annual reregistration of physicians in order to provide an investigator by the Board of Registration in Medicine. A two-dollar fee from each physician would yield approximately \$12,000 annually, he stated.

Dr F W Snow of Newburyport, Chairman of the Committee on Revision of By Laws, reported that the committee met on January 3, 1936. Dr Snow read the revisions, which were advised by the Committee, and it was moved and seconded that the recommendations be accepted.*

It was moved that the communities within the jurisdiction of the Essex North District Medical Society be grouped as follows, for the organization of the Committee on Public Relations:

- 1 Lawrence
- 2 Methuen
- 3 Haverhill, Groveland, Georgetown, Merrimac, Boxford
- 4 Andover, North Andover
- 5 Amesbury, Salisbury
- 6 Newburyport, West Newbury, Newbury, Rowley

Dr Burnham objected to the splitting up of the Greater Lawrence district, the objection was not carried, and the original motion was seconded and unanimously adopted.

After explanatory remarks, Dr Edward Mack Smith moved that a committee of five, not officers and not residents of Lawrence, be appointed by the Chair (a member ex officio) to report, with a request to publish, whether the constitution has been followed in recent Board of Trial cases. The motion was seconded and unanimously adopted.

In the reports of the City Committees, the study of the City Physicians in Haverhill was presented. It was brought out that the three City Physicians in 1935 made approximately twelve thousand calls with an average gross compensation of fourteen and one-half cents per call.

Studies on free work by the Staff of the Gale Hospital showed that on a conservatively estimated free basis, the physicians were contributing over eighty thousand dollars' worth of service to the city's poor each year without receiving any financial return.

The Committee felt that some of the work now being done by the City Physicians could properly be transferred elsewhere, that ultimately the inadequate compensation for this work must be considered if the city arrives at the position of being able to pay a fee basis for services rendered.

*See Appendix

A "panel" system was suggested whereby the patient could choose from a list of physicians who were willing to do this work on a reduced fee basis. It was also recommended that a central office be provided to facilitate the work of the City Physicians.

By unanimous consent of every physician in the city, lodge practice will not be carried on by any physician.

The meeting adjourned at 5 P M

E S BAGNALL, M.D., *Secretary*

APPENDIX

Revisions of the By Laws of the Essex North District Medical Society Recommended by the Committee on the Revision of By-Laws

ARTICLE I

(Unchanged)

Fellowship

The Society shall be called the Essex North District Medical Society and shall consist of all the Fellows of the Massachusetts Medical Society credited to it by the latter, and residing in the cities of Haverhill, Lawrence and Newburyport, and in the towns of Amesbury, Andover, Boxford, Georgetown, Groveland, Merrimac, Methuen, Newbury, North Andover, Rowley, Salisbury, and West Newbury, and also all other Fellows credited by the Massachusetts Medical Society and residing elsewhere.

ARTICLE II

(Changed)

Meetings

SECTION 1 There shall be held each year the three stated meetings of the Society, on a Wednesday in January, May, and October respectively. The meeting in May shall be the annual meeting, and shall be held on or before the fifteenth of the month.

SECTION 2 Special meetings for social, scientific, or other purposes may be called, from time to time, by the President on his own initiative, or at the written request of five members. At a special meeting, there shall be transacted only such business as is specified in the call of the meeting.

SECTION 3 (A) At the annual meeting, there shall be elected by ballot the officers of the Society, as provided for in Article III, the Councilors, the Censors, the Committee of three on Funds, a Commissioner of Trials for the Massachusetts Medical Society, a Correspondent to the official organ of the Society, a Committee on Public Relations, a Delegate to the Public Relations Committee of the State Society who shall serve as chairman of the District Public Relations Committee, all of whom shall hold office for one year, or until their successors are elected.

(B) The Councilors shall be elected in number equal to one for every thirty active and retired Fellows, and a majority fraction thereof as of January 1. One Councilor and one Alternate shall be designated by the nominating committee to act as members

of the nominating committee of the Council.

(C) The Censors shall be five in number and must be elected from members of at least ten years' fellow ship. One Censor who must also be a Councilor shall be designated by the nominating committee as Supervisor.

(D) All officers and members of the committee shall assume office on the day of election.

(E) At the annual meeting the nominating committee, the treasurer and the auditor shall present their respective reports.

SECTION 4. Five members shall constitute a quorum but a less number may adjourn the meeting from time to time.

ARTICLE III

(Changed)

Officers

The officers shall consist of a President, a Vice-President, Secretary, Treasurer and Auditor. One Fellow may serve as Secretary and Treasurer.

ARTICLE IV

(Formerly Article V—except for last sentence which was stricken out)

Duties of the President and Vice-President

The President shall call to order and preside at all meetings of the Society and shall have all the powers usually accorded to a presiding officer. He shall also perform such other duties as may devolve upon him as Vice-President ex-officio of the State Society.

In the absence of the President, his duties shall be discharged by the Vice-President and in the absence of both these officers, a chairman shall be chosen by the Society.

ARTICLE V

(Formerly Article VI—except for last sentence, which was stricken out)

Duties of the Secretary

The Secretary shall have charge and custody of the By-Laws, Records and other papers of the Society. He shall send to each member a printed notice of each meeting of the Society and keep a fair record of all its doings, and read at the meetings all such communications as the President may direct to be made, he shall notify the chairman of each committee appointed by the Society in each case stating the commission and names of the committee, and he shall perform such other duties as may be assigned to him or as are required by the By-Laws of the Massachusetts Medical Society or by any vote of said Society or its Councilors.

ARTICLE VI

(Replaces former Article VII)

Duties of the Treasurer

The Treasurer shall collect all moneys due the Society except such as are otherwise especially provided for. He shall keep an accurate account of all receipts and disbursements and shall make disbursements for all routine expenses under the authority of the Executive Committee or as may be ordered by vote of the Society in any regular meeting assembled. He shall annually make to the Society

a written report of the state of the treasury and shall subject all his accounts to the inspection of the Auditor. He shall also perform the duties required of him by the By-Laws of the Massachusetts Medical Society or by any vote of said Society or its Councilors. He shall act as Secretary of the Committee on Funds but without a vote.

ARTICLE VII

(Replaces former Article VIII)

Of the Invested Funds

The general care and management of the permanent funds of the Society including those now in hand and any that may hereafter be acquired shall be invested by the Committee on Funds,—subject, always to such directions as may be given from time to time by the Society.

The duties of the committee in this regard shall be

1. To treat each separate gift or legacy or other acquisition designed for permanent investment, from whatever source received as a separate and independent fund, designating it by either the name of the donor or some other indicative of the use to which it is made applicable.
2. To keep all such funds constantly invested in interest bearing securities having at all times in the selection of such securities particular regard to the safety of the principal rather than to the rate of interest to be obtained.
3. To expend, or cause to be expended at their discretion the income derived from these investments for the purposes authorized by the terms under which the several funds are or shall be held and for no other.
4. To keep in a book provided for the purpose an account current with each fund,—which book and account shall at all times be open to the inspection of any member of the Society who may desire to examine them.
5. To lay before the Society at every annual meeting in writing and in detail, a complete report of the transactions of the year preceding, stating for each fund the income received the expenditures made (and for what) its present condition, and the name, character and amounts of the several securities in which it is held.

ARTICLE VIII

(N. W.)

Public Relations Committee

SECTION 1. The Public Relations Committee shall consist of one representative from each community or group of communities as defined by the Society who will be elected by ballot. The Public Relations Committee is to study the relations of the Medical Profession and the Society with the Public and will make such recommendations as may be indicated, from time to time, and take such action as may be directed by the Society. It shall also serve as an executive committee and a nominating committee.

SECTION 2. Each community or group of communities, shall be represented by a local Committee on

Public Relations Members of these local committees shall be appointed by the Public Relations Committee

SECTION 3 The chairman of each local committee shall be a member of the Public Relations Committee

SECTION 4 The President and Secretary of the Society shall be members of the Public Relations Committee

ARTICLE IX

Amendment of By Laws

The Society shall, at its discretion, incorporate into its By-Laws at a stated meeting, by a majority vote and without previous notice, the substance of any vote or resolution passed by the Councillors of the State Society, and affecting the duties, rights or privileges of this Society, or of any of its officers. Otherwise the By Laws of this Society may be amended by an affirmative vote of two-thirds of the members present and voting at a stated meeting, provided that notice of the proposed amendment shall have been given in writing at a previous meeting, and notice of the same sent by the Secretary to each member of the Society

MASSACHUSETTS GENERAL HOSPITAL

A Clinical Meeting of the Staff of the Massachusetts General Hospital will be held in the Moseley Memorial Building, on Thursday, February 27, 1936, at 8 15 P M

PROGRAM

- 1 Artificial Menopause in the Treatment of Carcinoma of Breast G W Taylor, M D
- 2 Is It Angina Pectoris? H B Sprague, M D

Physicians, medical students, nurses and social workers are cordially invited

Committee on Hospital Meetings,

WILLIAM B BREED, M D, *Chairman*,

MARSHALL K BARTLETT, M D, *Secretary*

BOSTON CITY HOSPITAL

STAFF CLINICAL MEETING

Wednesday, February 26, 1936, at 8 15 P M, Cheever Amphitheater

Contributions of Medical Social Service to Diagnosis, Treatment and Prevention.

The Function of Medical Social Service Dr Merrill Moore and Miss Mabel R Wilson.

Case Presentations I. Surgical Social Problems Dr Charles C Lund II Medical Social Problems Dr George P Reynolds

The Patient in His Social Environment Dr George R Minot.

COMMITTEE ON HOSPITAL CLINICS

CLOVER HILL HOSPITAL

Lawrence, Mass

The next medical meeting of the Clover Hill Hospital will be held in the reception room of the hospital at 161 Berkeley Street, Lawrence, on Thursday evening, February 27, 1936, at 9 P M

Speaker Louis E Phaneuf, M.D, of Boston
Subject The Management of Uterine and Vaginal Prolapse

The lecture will be illustrated with lantern slides Discussion will follow All physicians of Lawrence and vicinity are cordially invited to attend

Clover Hill Hospital,

N F DECESARE, M D, *Chairman*

NEW ENGLAND HOSPITAL ASSOCIATION

The annual meeting of this Association will be held February 27, 28, and 29 at the Hotel Statler, Boston

On February 28 there will be a special section meeting for Trustees

AMERICAN SOCIETY FOR THE CONTROL OF CANCER

The Annual Meeting of the members of the American Society for the Control of Cancer will be held at the office of the Society, Room 1501, 1250 Sixth Avenue, New York, N Y, on Friday, March 6, 1936, at 3 30 P M

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, February 25, at 8 15 P M

PROGRAM

Presentation of Cases

Spontaneous Hypoglycemia By Dr Russell M Wilder, Mayo Clinic, Rochester, Minnesota.

Medical students and physicians are cordially invited to attend

MARSHALL N FULTON, M D, *Secretary*

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Memorial Hospital, Worcester, Mass (Knowles Hall, Nurses' Home), Monday, February 24, 1936, at 8 00 P M

PROGRAM

- 1 Effects of Contagious and Infectious Diseases on the Heart

A. General Statement of Main Topic Dr O H Stansfield

B Late Results of Contagious and Infectious Diseases on the Heart Dr E H Haloran

- 2 Acute Benign Pericarditis Dr F B Carr

- 3 Coronary Symptoms in Pernicious Anemia Dr J J Dumphy

All members of the New England Heart Association and interested physicians are invited to attend

JAMES M FAULKNER, M.D, *Secretary*

THE NORFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the Society will be held in the Massachusetts Memorial Hospitals, 82 East Concord

Street, Boston Tuesday evening February 25 1936
at 7 00 P M

PROGRAM

7 8 15 P M

Inspection of new building (Especially the operating rooms and viewing gallery)
Demonstration of Mechanical Heart. Dr George Layens
Demonstration of Electrocardiograph. Dr William Reid.

8 15-10 P M

Address of Welcome. Dr Henry Pollock, Superintendent, Massachusetts Memorial Hospitals

The Clinical Diagnosis of Hyperthyroidism. Dr Howard Clute
Congenital Factors in Urinary Infections. Dr Samuel Vose.

Is There an Inheritable Tendency to Practice Medicine Successfully? Dr Reginald Fitz.
Complications in Mumps. Dr Conrad Wesselhoft.

10 00 P M

Refreshments—Talbot Memorial
FRANK S. CROIGHAN, M.D. Secretary

CARNEY HOSPITAL

CLINICAL MEETING

The next clinical meeting of the Carney Hospital will be held on Monday February 24 at 8 30 P M

Subject Thoracic Surgery by Dr John Strieder (Lantern Slides)

Physicians and medical students are invited to attend

SOCIETY MEETINGS, CONGRESSES
AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY FEBRUARY 24 1936

Monday February 24—

8 30 P M. Carney Hospital Clinical Meeting.

Tuesday, February 25—

9 10 A.M. Boston Dispensary 5 Bennet Street, Boston Case Presentation. Dr Francis McDonnell.

9 30 P M. Pediatric Ward Visit Massachusetts Eye and Ear Infirmary.

7 P M. Norfolk District Medical Society Massachusetts Memorial Hospitals, 83 East Concord Street Boston.

8 15 P M. Harvard Medical Society Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance)

Wednesday February 26—

9 10 A.M. Boston Dispensary 5 Bennet Street, Boston. The Present Role of the General Surgeon in a Modern Hospital. Dr Hubert F. Day

113 A.M. Clinico-Pathological Conference Children's Hospital.

8 15 P M. Boston City Hospital Staff Clinical Meeting Cheever Amphitheatre.

Thursday February 27—

New England Hospital Association. All day session Hotel Statler, Boston.

8 30 9 30 A.M. Clinic Surgical and Orthopedic Staffs of Children's Hospital at the Children's Hospital.

9 10 A.M. Boston Dispensary 25 Bennet Street Boston Diabetic Clinic. Dr Jacob Schloss

9 30 P M. Medical Clinic at the Peter Bent Brigham Hospital.

8 15 P M. Massachusetts General Hospital Clinical Meeting of the Staff Moseley Memorial Building.

Friday February 28—

New England Hospital Association. All day session. Hotel Statler Boston.

9 10 A.M. Boston Dispensary 25 Bennet Street, Boston. Physiological Adventures Abroad. Dr G. Philip Grabfield
13 M. Massachusetts General Hospital. Clinical Meeting of the Staff of the Children's Medical Service. Either Dome.

Saturday February 29—
New England Hospital Association. All day session. Hotel Statler Boston.

9 10 A.M. Boston Dispensary, 5 Bennet Street Boston. Presentation of Ward Case. Dr H. Magendanz.

COMMITTEE ON HOSPITAL CLINICS

CLOVER HILL HOSPITAL

Lawrence, Mass

The next medical meeting of the Clover Hill Hospital will be held in the reception room of the hospital at 161 Berkeley Street, Lawrence, on Thursday evening, February 27, 1936, at 9 P M

Speaker Louis E Phaneuf, M.D., of Boston
Subject The Management of Uterine and Vaginal Prolapse

The lecture will be illustrated with lantern slides Discussion will follow All physicians of Lawrence and vicinity are cordially invited to attend

Clover Hill Hospital,
N F DECESARE, M.D., *Chairman*

NEW ENGLAND HOSPITAL ASSOCIATION

The annual meeting of this Association will be held February 27, 28, and 29 at the Hotel Statler, Boston

On February 28 there will be a special section meeting for Trustees

AMERICAN SOCIETY FOR THE CONTROL OF CANCER

The Annual Meeting of the members of the American Society for the Control of Cancer will be held at the office of the Society, Room 1501, 1250 Sixth Avenue, New York, N Y, on Friday, March 6, 1936, at 3 30 P M

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, February 25, at 8 15 P M

PROGRAM

Presentation of Cases
Spontaneous Hypoglycemia By Dr Russell M. Wilder, Mayo Clinic, Rochester, Minnesota.

Medical students and physicians are cordially invited to attend

MARSHALL N FULTON, M.D., *Secretary*

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Memorial Hospital, Worcester, Mass (Knowles Hall, Nurses' Home), Monday, February 24, 1936, at 8 00 P M

PROGRAM

- 1 Effects of Contagious and Infectious Diseases on the Heart

A. General Statement of Main Topic Dr O H Stansfield

B. Late Results of Contagious and Infectious Diseases on the Heart Dr E H Haloran

- 2 Acute Benign Pericarditis Dr F B Carr

- 3 Coronary Symptoms in Pernicious Anemia Dr J J Dumphy

All members of the New England Heart Association and interested physicians are invited to attend

FEBRUARY 27, 1936

NUMBER 9

CANCER OF THE RECTUM AND SIGMOID

DR. E. PARKER HAYDEN, M.D. †

THE basis of this paper is a series of eighty one cases of cancer of the rectum and sigmoid which have come under my care in private practice, or on which I have operated at the Massachusetts General Hospital in the past nine years (table 1). Of the cases seen in private practice, fourteen had radical operations elsewhere, either before or after coming under my observation. Eleven of these are dead. Three are living for periods of eight years, two years, and three months after operation

TABLE 1
CANCER OF RECTUM AND SIGMOID
81 Cases

Radical excisions	51
Local excisions	3
Palliative operations	10
No operation	3
Operated elsewhere	14
Total	81

Of the remaining patients, sixty seven in number, three advanced cases did not come to surgery. I operated upon sixty four cases as enumerated in the accompanying tables. Of these, three showed an extremely early malignant degeneration of an adenomatous polyp and were treated only by local removal of the polyp for individual reasons outlined below under the subheading of "Early Cancer in Polyps."

There remain sixty-one cases, of which fifty one were subjected to radical removal of the growth and gland bearing areas, according to one of the several accepted procedures, and ten cases were explored and found to be inoperable. Thus, out of sixty seven cases, the growth was removed in fifty four giving an apparent operability rate of eighty per cent. This figure, however, is not quite a true expression of the facts, because those patients operated upon at the Massachusetts General had been selected from an indefinite larger group as being suitable for operation. It is safe to say, however, that sixty five per cent to seventy per cent would represent approximately the true operability rate.

The total operative mortality was 15.4 per cent, which coincides closely with figures reported by several other writers in connection

with the same percentage of operability. A narrower selection of cases, excluding those in the older age group, and excluding the more advanced cases, would lower the operative mortality rate, but would offer relief from pain and a possibility of cure to a smaller number of sufferers from the disease.

A glance at table 4 will show that several cases died in from four to eight months after operation. In these patients the disease recurred rapidly, perirectal involvement being present at operation, and in three cases there had been a perforation with small abscess at the time of operation. I am sure that, in these instances the remaining months, though few, were spent more comfortably, with the growth removed, than would have been the case otherwise. Also, in table 5, one sees that of the eight patients who died in the hospital six were over sixty five years of age. One had a very extensive growth involving both ileum and uterus and two others had perirectal involvement. The odds were rather against these people though a two-stage procedure, in several cases, might have made a difference. One cannot compare mortality based on a high operability rate with mortality in a carefully selected group of cases, unless due allowance is made for all factors concerned. A summary of some comparative statistics on this point, from publications of other surgeons, may be found in a previous article.¹

CASES TOO ADVANCED FOR REMOVAL OF GROWTH

It is impossible in most instances to estimate accurately the operability of these tumors by any examination short of intra abdominal exploration. Thus it happens that one is often able to remove, apparently completely, a growth which on rectal examination had seemed very large and immovable, whereas, in another case, a much smaller tumor may prove to have already metastasized or invaded adjacent structures to an extent that would preclude any attempt at removal. As shown in table 2, ten of the thirteen inoperable cases were explored and colostomy performed in eight of these. The transverse colon was utilized in two cases, because of extensive pelvic involvement making it impossible to bring out a loop of descending colon. In two other cases because of the patient's situation at home, and the fact that immediate obstruction seemed unlikely, exploration without colostomy was done. To bring out

†Hayden, E. Parker—Assistant Surgeon, Massachusetts General Hospital. For record and address of author see "This Week Issue," page 436.

a loop of colon later on, under novocaine anesthesia, in the event of obstruction developing, would have been a simple procedure. As a matter of fact, one of these patients died without obstructing, and the other is still alive and as yet unobstructed. The ten cases explored were deemed inoperable on the basis of either extensive lateral pelvic wall involvement, invasion of bladder and ureters, metastasis to mesocolic nodes above the origin of the left colon

artery, extensive liver involvement, or a combination of these conditions. One woman had an independent carcinoma of the cecum also. One or two small liver nodules, though meaning eventual death, need not be a contraindication to palliative radical resection. A striking example of the truth of this point was brought to my attention by Dr. D. F. Jones, who related the story of a patient on whom he had performed an abdominoperineal resection in the presence of several small but definite liver metastases. Four and a half years later the man came to his office, having only recently been obliged to give up the work which he had been doing steadily since his postoperative recovery. His liver almost filled the abdomen, and death occurred shortly thereafter.

RADICAL OPERATIONS

In this group of fifty-two patients six different operations were employed. The first ten cases were done in two stages. Since then, with increasing experience, the tendency has been to do more single-stage operations. An analysis of the various types of operations used is set forth in table 3. This table includes, besides the fifty-one cases of cancer, one case of large benign adenoma in which a radical operation was done. The rationale of this procedure in the one benign case will be discussed later.

Of the six different operations employed in this series, abdominoperineal resection, in one or two stages, was used in forty-one of the fifty-two cases—about eighty per cent. There are several two-stage abdominoperineal operations, all of which have certain advantages and disadvantages, but I have used only the Jones² opera-

tion in the eleven cases listed in table 3. The one-stage procedures were performed according to the technique of Miles³, the perineal part of the operation being carried out with the patient in right Sims' position. All one-stage cases were transfused at the end of the operation, in order to give them an extra boost, and to minimize the shock which sometimes results

TABLE 3
RADICAL OPERATIONS

from this extensive procedure. The colostomy was established through a short left lateral rectus incision in most cases, and the long paramedian incision closed without drainage. In some instances, however, with a short mesentery, it is easier to bring the bowel out through the median incision because of the median attachment of the mesentery.

I have usually sutured the colon to the left parietal peritoneum so as to obliterate the aperture lateral to the colostomy. The small bowel may otherwise herniate and become obstructed. In several instances, also, I have sutured the internal openings of inguinal herniae from within the peritoneal cavity, without, of course, making any muscle or fascia repair.

A simple colostomy, with posterior resection at a later date, is probably the safest operation for rectal cancer one can do, but it is not possible to carry out posteriorly as complete and careful a removal of pelvic mesocolon and other gland-bearing areas in the pelvis as can be done in an abdominoperineal operation. However, posterior resection, for low growths in poor risk patients, is a good operation.

Anterior resection, with inversion of the rectal stump, and end colostomy, is the operation of choice when the tumor is high enough to

permit dissection well below it, but not high enough to allow a resection with direct suture, or a Mikulicz procedure. The rectal stump should be left within the peritoneal cavity not behind it, lest retroperitoneal sepsis occur. This remaining lower segment, usually about three inches in length can be excised posteriorly later if the margin of safety below the tumor has been such as to make it seem wise.

Coexistent Pathology

It has always seemed wise to resist the temptation to remove an appendix which often presents itself in the field of operation and some times actually impedes the packing upward of the cecum and small bowel. In one case a large Meckel's diverticulum, adherent in the pelvis was freed but not removed. The added time required for removal and the added risk of infection, in an operation already extensive are good reasons for deciding against removal of either of these appendages.

I am sure no one would ever consider favorably the extirpation of a gallbladder filled with stones in conjunction with a pelvic operation of this magnitude. In several cases in this series marked cholelithiasis did exist apparently without symptoms before or since the resection.

In females, prior to their menopause it is probably wise always to cut and tie the tubes, but I have never seen any reason for removing the ovaries, unless cystic or adherent to the tumor. The uterus, retroverted makes a firm support to which the lateral pelvic peritoneal flap can be sutured in the construction of a new pelvic floor. None of my patients in whom this was done have complained later of any symptoms, such as backache, which is sometimes attributed to retroversion but is usually due to other causes.

In two instances, where the uterus was firmly adherent to the tumor I have done a hysterectomy removing the uterus and tumor en masse. This will seldom be necessary, however. Enucleation of two or three small subserous fibroids was done on one occasion without prolonging the operation appreciably.

A most striking case with respect to coexistent pathology, was that of a man of fifty three who had had severe nightly attacks of asthma for nineteen years, glycosuria bordering on a true diabetes, an old syphilis apparently adequately treated, and exophthalmic goiter of over a year's duration with metabolism up to plus forty. After ten days on Lugol's solution with very little effect a subtotal right hemithyroidectomy was done. Difficulty with anesthesia and high pulse rate made it seem wise not to touch the left lobe. This operation brought the metabolism down to plus eleven and the attacks of asthma ceased. Two weeks later a one-stage abdominoperineal resection was done without difficulty and the convales-

cence was normal. There was no return of the asthma until a month after the last operation, but the attacks have gradually increased since then. This patient has resumed his work as editor on the staff of a daily paper for some months now, working full time, and with no recurrence of either hyperthyroidism or cancer as yet. The attacks of asthma, however have become about as severe and frequent as formerly.

In the preliminary search of the abdomen for metastases, prior to embarking on the actual resection, one should palpate carefully the whole colon for other independent carcinomas or polyps. If a second cancer is present it must, of course, either be dealt with at the time, or perhaps more safely at a second operation not too distant. One case in this series did have an independent cancer in the cecum as previously stated, but was inoperable from the standpoint of the rectosigmoid growth. The cecal tumor was only three or four centimeters in diameter and could have been resected easily under other circumstances. It is desirable also, to know of the existence of simple polyps because of their tendency to become malignant at a future time. I have recently been shown a case, operated by a one-stage resection, with end colostomy, in which a good sized and unsuspected, polyp prolapsed from the colostomy several days after the resection. It was a simple matter for the surgeon to remove it without metastasis of any sort.

Points in Technique

Abdominoperineal resection can be done with equal ease through a left or a right paramedian incision which should extend just above the umbilicus to give adequate exposure. A high Trendelenburg position is a great help if it does not hamper the patient's respirations. Spinal anesthesia gives perfect relaxation but there is always the uncertainty as to its duration and for this reason I have used ether in most cases. Large square pads are most useful in securing a good walling off of all the intestines except the lower descending colon and sigmoid. A Balfour self retracting retractor with deep supra pubic blade facilitates the operation by freeing the assistants' hands for other purposes. The deep blade will retract bladder or uterus.

Since it is very necessary to have adequate peritoneum for the construction of a new pelvic floor after the abdominal dissection is finished it is essential to estimate the possibilities in this respect before starting to construct lateral peritoneal flaps from the mesosigmoid. If the uterus is to be used in closure the flaps need not be so long. Also if the back of the bladder is free from any question of tumor involvement, a surprisingly good peritoneal flap can be constructed from this region in the male and drawn backward to join the lateral flaps.

Eleven inch, blunt pointed, straight and curved scissors are most useful instruments in the deep pelvic dissection necessary. In addition to their convenience for deep cutting, they are even more useful as a dissecting tool when closed. Planes of cleavage posteriorly and anteriorly can be readily developed down to the coccyx behind and to the prostate or below the cervix in front. Laterally, the rectal stalks must be cut, but this can be done without much bleeding and often without the necessity of any tying. The lower these stalks are divided, the easier the perineal part of the operation will be. In cutting these lateral supports, great care must be taken not to cut the ureters close to the bladder. There should be no difficulty in visualizing them above this point, and the dissection should then progress downward with the two ureters as the lateral boundaries.

After ligation of the superior hemorrhoidal artery and vein just below the origin of the left colic, and ligation of the sigmoidal artery and the sigmoidal branches of the left colic, the mesocolon is divided up to the bowel wall, if the operation is to be completed in one stage. I have found the quickest method of dividing the bowel to be as follows: rubber covered or wire clamps are applied to the bowel six inches apart, above and below the point of resection. Then two heavy silk threads are tied tightly around the bowel three-quarters of an inch apart, the bowel severed with a cautery between the ties, and the puckered mucous membrane of the two ends well cauterized. A four inch square of rubber dam is then placed over each end and tied around with another heavy silk tie. I have had no trouble from using this method, and it eliminates the suturing necessary when the bowel is severed between crushing clamps. The ends, protected by rubber, can be handled freely.

Use of the right Sims' position in the perineal part of the operation, for a right-handed operator, affords definite advantages. After closure of the anus, an incision is made encircling the anus and extending up to the level of, but lateral to, the coccyx, and the coccyx is disarticulated. There is always to be found a firm attachment of the levators and coccygei to the presacral fascia just above this point. A sweep of the scalpel laterally just under and anterior to the sacrum will divide this attachment and admit the index finger to the cavity developed during the abdominal part of the procedure. It is then very easy to sweep the index finger around laterally between rectum and levators on each side and cut the levators with scissors while the finger as a guide shields the bowel from harm. If the rubber covered distal end of gut has been carried down behind the rectum from above, it can be easily felt and hooked out with the finger and all of the previously freed sigmoid and rectum delivered outside as a long

handle on which traction is exerted with the left hand as the dissection is continued *from above downward* in the now easily visible plane of cleavage between prostate and rectum or posterior vaginal wall and rectum, and the specimen removed.

After tying the necessary bleeders, and reducing ooze to a minimum, the large cavity is drained by a rather lightly packed gauze roll inside of a sheet of rubber dam, brought out anteriorly in the perineal incision, and the wound sutured.

Postoperative Course

I have usually removed the gauze on the third or fourth day and the rubber a day or two later. The colostomy is opened after twenty-four or forty-eight hours, or if there has been any obstruction, it is opened at the close of the operation. A vent for gas is thus obtained, but irrigation of the bowel is probably best delayed until the third or fourth day. The posterior wound is irrigated with saline as necessary.

A catheter is inserted in the bladder before operation, kept in place for eight to ten days and after removal is reinserted at eight hour intervals for several days or longer according to the amount of residual. Some degree of bladder sepsis is difficult to avoid.

If no complications ensue, the patient can start getting up in two weeks and is ready to go home in from three to five weeks after operation.

Results

Accurate details on end results are set forth in tables 4, 5 and 6. In table 4 are tabulated the people who have died since leaving the hospital. Twelve of the twenty had either perirectal glandular metastases or perforation of the bowel, or both, at the time of operation, and in four others we did not have definite data on this point. It is therefore not surprising that nine cases died in less than a year after discharge from the hospital. On the other hand, eleven lived over a year, one for five years and ten months, and another, with extensive regional metastases at time of operation, lived three and a half years and worked during most of that time. Most of the more malignant tumors also occurred in this group (table 4).

In table 5 are listed the cases that died in the hospital. Pulmonary complications and intestinal obstruction accounted for six of these deaths. One death (case 50) was due to peritonitis from a small intestinal anastomosis leak, following an extensive resection in a very advanced case with enterocolic fistula. The remaining patient (case 22) died at the close of an easy second stage which had been delayed for twelve days because of a heart condition. We felt that spinal anesthesia contributed to

the death in this case but could not secure an autopsy

There are twenty-four patients living without definite evidence of disease, and in most cases free from any symptoms and in excellent health (table 6). Some of the later ones, of course, will recur. Three have survived for five years, two for four years, five for three years, three for two and a half years, and four others over a year. Seven were operated upon within the past year. It is significant that of the ten cases alive and well for three years or more *none had regional metastases*. Also, in these twenty-four cases, there were only four in which the tumor was graded as highly malignant.

SINGLE AND MULTIPLE ADENOMAS

There is abundant evidence to establish beyond doubt the importance of adenomas of the colon and rectum as precancerous lesions. That they are capable of producing bleeding, while still benign, is also certain. And so, for both of these reasons, it is desirable to remove them when possible.

Adenomas Beyond Reach of the Proctoscope

In the investigation of a source of bleeding from the bowel, one must always consider the possibility of polyp or cancer higher up when proctoscopy fails to reveal either condition in rectum or sigmoid. If a barium enema shows no cancer, and a contrast enema fails to demonstrate any polyps, and if internal hemorrhoids and other sources of bleeding have been excluded, there arises a real problem in trying to decide whether to adopt a policy of watchful waiting or to explore the abdomen. This decision must be based on the likelihood of the patient having cancer. If the general condition and history suggest this possibility quite strongly, exploration should certainly be advised. If, on the other hand, malignancy seems unlikely, it is better, in general, to delay operation because of the rather slim chance of being able to palpate a small polyp if present. Then, too, if a polyp should be felt through the wall of the colon, it need not necessarily be the source of bleeding, and there might be other polyps present. To open the colon, excise a polyp locally, and resuture the bowel is a procedure which, of course, opens up the possibility of peritonitis. This risk is justifiable only in selected cases.

Adenomas Visible Through the Proctoscope

A much simpler problem is presented in the definite localization of polyps by direct vision. Their removal, however, must depend on several considerations.

In the case of multiple polyposis, as determined by proctoscopy, the condition is likely to involve most if not all of the colon. The pos-

sibility of malignant degeneration, through sheer force of numbers, is high. Total colectomy, though not without risk, and though involving the establishment of a preliminary and permanent ileostomy, is still the only method of cure. Cancer is almost sure to develop in such a colon if the individual lives long enough.

When one or two or three polyps only are seen, their removal becomes relatively simple. Under these circumstances, however, two important questions arise: (1) Is the polyp, in fact, still benign? (2) If benign, is it of such size, shape, and location that it can be removed with safety through a proctoscope, or by use of retractors to secure an adequate exposure? A pedunculated polyp may be just becoming malignant, and a biopsy may or may not happen to catch the area of degeneration. Usually a polyp with definite, small, soft pedicle can be considered benign and may be removed in one of several ways: (1) A tie may be placed around the pedicle for hemostasis and the polyp then cut off distally, or allowed to slough off later on. (2) The pedicle may be coagulated by cautery or diathermy with or without immediate removal of the polyp. (3) The polyp, if more sessile, can be removed with excision of a surrounding area of normal mucous membrane and suture of the mucosal defect. This type of polyp is rather more likely to show early malignant change, and therefore a removal with area of normal mucosa is a safer procedure in case the subsequent pathological examination should show cancer.

Early Cancer in Polyps

I now have under observation a man of fifty-six in whom this type of removal of a one and one-half centimeter polyp low in the rectum was performed one and one-half years ago. The situation was made clear to him after the pathological report was returned, and he elected, with my approval, to remain under observation rather than to undergo a resection of the rectum at that time. There has been no recurrence as yet, either locally or otherwise.

A woman of sixty-two with coronary disease had a single adenoma easily accessible on the posterior wall of the rectum. A biopsy from several areas was reported as "mucous polyp." The lesion had a narrow, ribbon-like pedicle and was removed with an area of normal mucosa, and suture of the defect. This polyp measured two and one-half by two by one and one-half centimeters in size and was subsequently determined to be a malignant adenoma. This patient died a year or so later of intra-abdominal metastasis without local recurrence. Radical operation was not considered advisable because of her cardiac situation and poor general condition.

Any type of local removal is not without risk.

if the polyp is located above the peritoneal reflexion in the upper rectum. I have known of one case in which on attempt to remove such a polyp resulted in a perforation of the bowel which was observed and immediate laparotomy performed. Death resulted from peritonitis.

About one and a half years ago a patient of my own, aged sixty, with a history of intermittent bleeding, showed a raspberry sized pedunculated polyp at the end of a ten inch proctoscope. Biopsy showed no malignancy, but when repeated four months later, the report was "malignant adenoma." I could see no change in the gross appearance of the polyp. Laparotomy was performed, the polyp easily palpated and found to be about four inches above the peritoneal reflexion. It felt soft and freely movable. Its location was such that a Mikulicz resection would not have been possible. Resection with end-to-end suture could have been done with difficulty, but this would have been the least safe of any of the possible procedures. A tube resection would likewise have been risky. Any other operation would have included permanent colostomy. I therefore decided, in view of the known pedunculated nature of the polyp, to do a local excision. Rubber clamps were applied to the sigmoid above and below the polyp, and an inch long incision was made on the anterior wall of the bowel. The polyp, which was attached on the mesenteric side of the bowel, was easily delivered into the incision in the bowel and was excised with a border of mucosa and the defect sutured. The bowel incision was then carefully sewed and the abdomen closed without drainage. The polyp measured one and one-half by one and two-tenths by one centimeter in size. This patient is now free of symptoms a year later and will probably remain so. In her case, considering all factors, a local removal of this polyp just becoming malignant, seemed justifiable. As a general principle, however, radical operation should be applied to even the smallest cancers.

Radical Operation for a Large Villous Adenoma.

Several months ago a man of fifty-two presented the largest benign adenoma of the rectum I have ever seen. It was attached to the anterior and lateral walls of the rectum over the bladder, and had a broad base. The tumor measured six and one-half by six and one-half by three and one-half centimeters in size, and the attachment to the bowel was three and one-half centimeters in diameter. Biopsies on three occasions were returned as negative for malignancy. Despite this fact, it seemed best to advise radical removal for two reasons. (1) The center of the area of attachment might well be malignant and in any event there was great likelihood of this large tumor soon becoming malignant. (2) Local removal was unsafe and almost impossible because of its location

against the bladder and because of the diameter of the base of the tumor. Knowing all the facts, then, the patient acquiesced, and a single stage abdominoperineal excision was performed. Subsequent examination of the area of attachment of the tumor still failed to reveal any area of malignant change. Knowledge of this fact was received by the patient with a great feeling of relief rather than with any feeling that perhaps a less radical procedure should have been carried out. This is the only instance in which I have performed a radical operation for a benign adenoma (fig. 1).

FIG. 1

BENIGN ADENOMA.

6.4 x 6.4 x 3.4 cm. in size with short, broad pedicle 2 1/2 cm. in diameter. Lower border 5 cm. above anus.

UNUSUAL TYPES OF EXTENSION AND METASTASIS

Perirectal Adenocarcinoma.

I have had two cases in which the carcinoma though it must have originated from the depths of a mucosal gland possibly from a small diverticulum nevertheless had extended entirely perirectally, producing, in each case, a stenosis in the rectosigmoid region with only normal mucous membrane visible by proctoscope. There had been no bleeding in either. Definite diagnosis, in each case was made by intra-abdominal biopsy and frozen section. In one case resection was not feasible because of a firm collar of tumor around the bowel and involving the bladder. In the other case, number thirty-five in the series, the growth was higher, and resection was carried out. In fig. 2 the point of biopsy can be seen lateral to the bowel and above the peritoneal reflexion. With the specimen opened up (fig. 3) the tumor encircling

the bowel and the normal mucosa can be seen. This was a grade three colloid cancer, and the patient died in six months of extensive intra-abdominal recurrence. It should be said also, that the possibility of these two tumors being

detail, with points on operative technique and an analysis and tabulation of end results in those cases subjected to radical operation.

The apparent cures consist largely of the cases with no perirectal involvement at time

FIG 2

PERIRECTAL ADENOCARCINOMA (Case 35)

metastatic was definitely eliminated by careful exploration at operation.

Distant Bone Metastases

It is quite unusual for tumors of the colon and rectum to metastasize to the skeletal system, though a few cases have been reported. Metastatic adenocarcinoma in the bones originates, in most cases, from a tumor primary in either the breast or the prostate. It is therefore of interest that in case twenty-four of this series, metastases occurred in the left clavicle, left humerus, spine, and ribs. Visible and painful nodules over the left sternoclavicular joint and over one of the left lower ribs made evident the site of two of the areas, and the others were demonstrated by x-ray.

CONCLUSIONS

A series of personal cases of cancer of the rectum and sigmoid has been presented in some

FIG 3

PERIRECTAL ADENOCARCINOMA (Case 35)

This tumor presumably originated from the depths of a mucous gland or possibly from a diverticulum and extended entirely perirectally. Normal mucous membrane throughout.

B—Anal outlet

of operation, and cases in which the tumor was graded as a malignant adenoma or adenocarcinoma grade two. The group of cases, dying later of recurrence, were more highly malignant, in general, and many had regional metastases at time of operation. On the other hand, there were enough conspicuous examples in which the reverse was true, to suggest the wisdom of a liberal standard of operability.

The problem of diagnosis and treatment of benign adenomas is also discussed.

CALCIFICATION IN THE ANNULUS FIBROSUS
OF THE MITRAL VALVE

BY JOSEPH H. MARKS, M.D.*

ROENTGENOLOGISTS have for years been interested in the problems of heart disease but recently this interest has been renewed and extended. The primary diagnosis of heart disease has for the most part remained in the hands of the internist but the roentgenologist has been of aid to the clinician in determining heart size and he has also given objective evidence of cardiac function or dysfunction with the aid of the fluoroscope he has been able to demonstrate abnormalities in rhythm. These aids to the cardiologist and internist have been dependent upon a study of the cardiac contour and upon examination of the lung fields for evidence of decompensation, little or no attention has been paid to the possible demonstration of the heart valves or other intracardiac structures, although the pathologist has known for years that calcification might occur in the valve leaflets in the late stages of rheumatic heart disease and in other parts of the heart in certain degenerative processes.

In 1921 Klason¹ reported the first proved case of intracardiac calcification which had been demonstrated antemortem by x-ray. Since that time, and especially since the report of Saul in 1932², several groups of roentgenologists have become interested in the inner structure of the heart and a number of reports of antemortem demonstration of intracardiac calcification have appeared in the European and American literature. Surprisingly enough as Sosman and Wosika³ have pointed out the areas of calcification can be visualized with the same conventional model of fluoroscope which has been in use for twenty years the only necessary added factors being that the examiner make a careful search of the deeper parts of the heart through a small aperture and with the eyes fully accommodated. For a clear cut film record of such calcification in the living subject it is of course necessary to have the newer fast screens and fast films, a fine focus tube and a machine which is capable of delivering relatively high milliamperage for short exposures.

Calcification has now been demonstrated in the living subject in the pericardium and in the coronary arteries in mural infarcts in the leaflets of the aortic and mitral valves, and in the annulus fibrosus of the mitral valve. No cases have been reported in which calcium was demonstrated in an intracardiac tumor during life but there is obviously no reason why such a demonstration cannot be made.

Up to the present time four cases have been reported in which calcification was demonstrated in the annulus fibrosus during life and subsequently proved by autopsy. One of these was reported by Klason in 1921¹, one by Fleischner in 1925⁴ and two by Saul in 1932. The case to be reported here is the first proved case to appear in the American literature.

M. C. Sosman of the Peter Bent Brigham Hospital has now made the diagnosis of intracardiac calcification in about 150 cases during life⁵ and he has reported proved cases in which the deposit of calcium was correctly localized antemortem in the valve leaflets⁶ and in the coronary arteries⁷. Yater and Cornell⁸ have recently reported a series of forty seven cases of complete heart block, nine of which showed calcareous deposits involving the bundle of His but in none of these was the calcium deposit demonstrated before death. Patients with heart block are therefore worthy of more careful study by the roentgenologist in the future.

It is of interest that approximately one third of the 150 cases seen by Sosman showed the calcification in the mitral annulus. Of the remaining cases about one-half showed the calcium to be in the mitral valve leaflets and about one half in the aortic leaflets but a few have been seen in which the calcium was in the coronary arteries and a few others in which it was in the pericardium. The calcareous deposits which occur in the mitral annulus are found in patients past middle life most of those reported being over sixty years of age, and the deposit is in all probability the result of a degenerative process. These cases do not give a history of rheumatic fever their hearts are usually well within the limits of normal size and they do not show clinical evidence of cardiac valvular disease. On the other hand many of the cases showing calcium in the valve leaflets give definite histories of rheumatic fever and most have definite clinical evidence of valvular disease. The clinical history is therefore of real help in the differential diagnosis of these two main types of intracardiac calcification further help is found in the difference in character and position of the calcium deposits. The deposit in the annulus is usually a mass of rather fine granules without the appearance of any definite structure although actual bone may occasionally be demonstrated in the histological sections, as in the case to be reported here. The deposits in the valve leaflets usually suggest dense masses without the finely granular appearance. The total mass of the calcium in the annulus is usually

Markes Joseph H.—Roentgenologist, Trueman Hospital Fall River, Mass. For record and address of author see This Week's Issue page 446.

much larger than that found in the valve leaflets and is therefore more readily seen, it is frequently sickle-shaped with the convexity downward and toward the left. If the calcification is within the valve leaflets the contour of the heart is of great aid in differentiating the mitral and aortic lesions. Other points of difference have been well brought out by Sosman and Wosika³

Calcification within the coronary arteries is more difficult to demonstrate during life but that it can be shown has already been proved⁶. The postmortem films of the case reported here show an amount of calcium within the coronaries which should be ample for antemortem visualization, it was probably overlooked simply because the interest was focused on the more readily seen mass in the mitral annulus.

CASE REPORT

Mrs. M. P., housewife aged seventy-two years, was first seen by Dr. William Mason on June 1, 1934 with a complaint of shortness of breath. She was admitted to the Truesdale Hospital on the same day.

Her past and family histories were not remarkable. She had been married fifty-three years and

Seven foot film of the chest showing rather marked cardiac enlargement, heavy hilar shadows and fluid at the right base.

had had one child who died shortly after birth there were no miscarriages. Husband living and well. Father died at seventy-five of 'heart trouble'. Mother died suddenly at seventy-eight. Two brothers living and well, aged sixty-three and seventy-four. There was no history of rheumatic fever.

The history of her present illness is rather fragmentary but apparently began about two years before, when she was awakened suddenly one night with a severe choking sensation, cough and shortness of breath, she spat up frothy sputum but no

blood. She was in bed two weeks at that time. Since then she has suffered from shortness of breath on exertion, there has been occasional palpitation, and she has, sometimes, been troubled with a feeling of tightness in the anterior chest which has been relieved by belching. There was no definite history of edema.

Physical examination showed a well-developed and well-nourished elderly woman who was orthopedic. Mucous membranes were slightly cyanosed. There was a well-marked arcus senilis. Retinal vessels showed moderate caliber changes and slight nicking at the arteriovenous crossings. The chest

Fast film at 30 inches showing the U shaped mass of calcium deep within the heart.

was barrel-shaped and the lungs were emphysematous. The left border of the heart was in the anterior axillary line, sounds of fair quality, rate about 100, rhythm regular, there was a short, apical, systolic murmur but no diastolic murmur. Radial vessels were thickened. Blood pressure 140/80. Liver edge was palpable about 7.8 cm below the right costal margin. There was moderate pitting edema of the legs and over the sacrum.

Röntgen examination on the day after admission showed rather marked cardiac enlargement both to the right and left with a small amount of free fluid at the right base. The lung markings around the hilum were heavier than normal and the supra-cardiac vessels were moderately dilated. Fluoroscopic copy showed a regular heart beat of poor quality. Deep within the heart and just to the left of the spine there was a U-shaped area of calcification, this mass was visible in all positions but was most clearly seen when the patient was turned so that the right chest was slightly forward. The open end of the U-shaped mass was directed upward, inward and backward and its limbs appeared to approximate each other during systole of the heart. Calcification was also seen in the aortic arch and in the descending aorta just above the diaphragm. Röntgen diagnosis was arteriosclerosis with cardiac hypertrophy, cardiac decompensation and calcification in the annulus fibrosus of the mitral valve.

Laboratory findings were as follows: RBC 4,120,000, hemoglobin 80 per cent by Tallqvist, WBC 6,400 with 86 per cent polymorphonuclears, NPN 26 mgm., blood sugar 80 mgm., Kahn negative, urine negative for albumin and sugar.

Clinical diagnosis was arteriosclerotic heart disease with congestive failure. She had not responded well to digitalis or to the usual coronary dilators at home and had been brought to the hospital.

for observation. She was quite comfortable in bed but died suddenly forty four hours after admission.

At autopsy there was about 900 cc. of clear fluid in the right pleural cavity and about 200 cc. in the left. There was also about 100 cc. of clear fluid in the pericardial cavity. Heart weighed 510 grams. Valve measurements were considered normal and

Postmortem film showing the granular mass of calcium in the mitral annulus and also showing the calcification in the coronary arteries.

were as follows: mitral 9.5 cm, aortic 8.0 cm, tricuspid 12.5 cm, pulmonary 8.0 cm. The left ventricular wall measured 17 mm in thickness and the right measured 9 mm. The descending branch of the left coronary artery was completely occluded and there was an infarct which measured 5 cm in diameter in the wall of the left ventricle. The ventricular wall in this area measured only 4 mm in thickness and there was a fibrinous clot attached to it. Both coronary arteries were markedly calci-

fied so that they were cut with difficulty and the lumen of the right was diminished in size. That portion of the annulus fibrosus which surrounded the mitral orifice was calcified except in its medial one-third. This granular mass of calcium when viewed from above was of the shape of a crescent having an internal diameter of 3 cm. and a thickness of almost 1 cm. in its widest part. There was a small amount of calcium at the base of the aortic cusps and there was marked sclerosis and calcification of the entire aorta. Other findings outside the chest included a small fibroid of the uterus and a single gall stone. Histological examination added little of interest except that a few areas of bone were demonstrated within the granular mass of calcification in the annulus.

COMMENT

The above report has been presented in order to record a proved case of calcification in the annulus fibrosus of the mitral valve which was correctly diagnosed by roentgen ray during life. It should be recalled that the annulus fibrosus is a figure-of-eight structure which surrounds both the mitral and tricuspid orifices, but the degenerative process which leads to calcification has been noted only in that portion which surrounds the mitral orifice, thus is perhaps related to the greater amount of work done by the left side of the heart.

It should be noted that these areas of calcification can be demonstrated with any fluoroscope using five milliamperes of current at about 25 kilovolts provided the examiner searches care-

Sketch and roentgenograph showing the mass of calcium extending to the wall of the heart from the base of the mitral valve leaflet. The aortic wall is shown above and the ventricular wall below. The pictures of bone fall to show in the left intergraph and to the right.

fully the deeper parts of the heart through a small aperture and with his eyes fully accommodated. It is well to begin at the auriculoventricular groove on the left border and then gradually move inward and downward at an angle of about forty-five degrees. If a mass of calcium is present, its characteristic dancing movement will be noted when the patient holds his breath. Once the mass is found, more accurate localization is made by gradually rotating the patient. Unless the heart rate is too rapid, the exercise of care and patience will be productive of good film records even though the more expensive, high speed equipment is not available.

That intracardiac calcification may be diagnosed during life and that this calcification may be correctly localized is of real interest to the cardiologist. Difficulty is frequently encountered in establishing the diagnosis of aortic stenosis clinically, but a roentgen demonstration of calcification in the aortic cusps dismisses all doubt. Likewise a demonstrable mass of cal-

cium in the annulus would aid in establishing the prognosis in cases of complete heart block. The internist and cardiologist may thus expect more from the roentgenologist in the future than a mere statement as to the cardiac size and contour and the appearance of the lung fields.

AFFAIRS IN CONNECTICUT

MEDICAL TESTIMONY AND DRUNKEN DRIVERS

During January the medical profession in Connecticut received an unexpected broadside when Joseph F. Grogan, President of the Connecticut Police Chiefs Association, and Michael A. Connor, Commissioner of Motor Vehicles, charged the physicians with conducting a racket in fixing drunken driving cases. The West Hartford Chief of Police stated that the \$50.00 which a doctor takes to pronounce a man in a borderline condition after the police physician has found him under the influence of liquor is just a racket. Commissioner Connor added, "Doctors must start practicing medicine and the lawyers must start practicing law instead of fixing cases."

These two gentlemen, in letters written by the President of the Hartford County Medical Association, were asked for specific instances of such alleged practices. To date Chief Grogan has not replied and Commissioner Connor has very lamely stepped back a few paces saying he meant nothing but encouragement to our profession. The *Hartford Courant* has taken up the controversy and in an excellent editorial calls attention to the unsatisfactory situation of providing expert medical testimony as it now exists in Connecticut.

The Board of Directors of the Hartford County Medical Association, feeling that the situation demanded concerted action by organized medicine, published the following statement in the Hartford press:

"According to recent articles in the local press, physicians in Hartford are said to be making a

'racket' of examining the so-called drunken driver. The board of directors of the Hartford County Medical Association feels that these accusations may be entirely unjustified and our board feels impelled to make a public statement concerning this situation.

"The whole matter of expert testimony has been a source of great dissatisfaction to the medical profession for many years. In many European countries expert testimony is provided by the Court itself, physicians and other experts being selected by the court, whereas in this country technical testimony is offered by each party to the controversy. This gives rise to the unfortunate spectacle of hired experts of opposing sides differing in their opinions for reasons which seem to the public to be other than honest differences of opinion.

"The Connecticut State Medical Society is at the present time investigating the possibility of altering our current practices by having expert testimony provided by the Court itself, though not denying to either party the right to bring in its own experts.

We believe that no satisfactory solution of the present problem of the examination of so-called drunken drivers will be reached until medical examination of such persons is made obligatory and the examination is made by a court appointed and court paid physician. Such a physician will then be testifying on behalf of neither prosecution nor defence but solely for the information of the court.

"In this connection it must be remembered that at present any so-called drunken driver, if he so wishes, may refuse to submit to any medical examination and it would seem that the law should be changed to make such examination obligatory.

"We would call to the attention of the authorities the fact that our County Medical Association has duly constituted committees to handle matters of medical ethics which involve any of its members. We would suggest that the county association be

NEW ENGLAND SURGICAL SOCIETY

UROLOGIC ASPECTS OF VESICOVAGINAL FISTULA*

BY WILLIAM C. QUINBY, M.D.†

A SINGLE woman aged forty-six years entered the Peter Bent Brigham Hospital in June 1935 complaining of leakage of urine following a total hysterectomy which had been done a year before for fibroids. The note of operation on the fourth of June is as follows:

Since previous operation the patient has been seen on several occasions and it has become evident that she is suffering from a vesicovaginal fistula as the cause of her incontinence of urine. The opening seems to be a very minute affair high on the anterior vault of the vagina and very hard indeed to see because of the absence of the uterus and a nulliparous condition of the parts. The bladder was opened today through a midline supra-pubic incision and above the interureteral bar there was found a slightly depressed area somewhat puckerred at the level of the upper limit of the vagina through which a fine probe could be passed. This sinus tract was surrounded by a circular incision through which an attempt was made by right angle dissection with scissors to deliver the bladder free from the subjacent vagina. This was done in an only partially satisfactory manner on account of the scar beneath. The bladder mucous membrane was closed by two fine sutures of catgut and the bladder wall united in the usual way a tube being left in the upper angle of the wound. With the patient in the lithotomy position an attempt was then made to reach the sinus from the vaginal side and again although it was possible to free the tissues somewhat, entire relaxation was not obtained on account of scarring. One or two silk sutures were placed however in the hope that they would permit the vagina to heal separately from the bladder.

The wound of operation healed without event and the patient was discharged on the eighteenth post-operative day. She still had some difficulty in urinary control but whether this was due to relaxation of the sphincter or to persistence of the fistula it was impossible to determine because extreme tenderness of both urethra and vagina made examination very difficult.

About a month after discharge the patient appeared for follow-up examination. Her incontinence had been much benefited by the operation but was still present in moderate degree especially on coughing or sneezing. Cystoscopy examination showed in the area of operation a small granulating spot as evidence of failure to heal on the part of the bladder. In order to stimulate this it was carefully fulgurated by an electrode. Today the patient returns reporting herself entirely dry and on investigation there is absolutely no longer any evidence of lack of healing in the bladder floor. There is no cystitis and although rarely the patient has slight urgency of urination, she is absolutely dry and very much pleased.

The first deduction to be drawn from this case is that the failure to get primary heal-

ing was without doubt due to an insufficient operative mobilization of the tissues. This is in part to be ascribed to the density of the scar at the upper end of the vagina which followed the total hysterectomy. Because of the nulliparous vagina with absent cervix a transvesical approach was proper but, on opening, the bladder mobilization was not carried out extensively enough to allow approximation without tension. Hence healing was not quite perfect. Fortunately stimulation by the fulgurating electric current through a cystoscope was sufficient to bring this about. We may note further therefore that when the fistulous tract is very small closure can be accomplished by this means.

A second case is that of a woman of thirty-six years who entered the Brigham Hospital on October 8, 1929 complaining of incontinence of urine, a painful bladder and during the past seven months the occasional passage of gravel.

Her first delivery was five years earlier by Caesarian section. Two subsequent pregnancies followed at yearly intervals at which high forceps were used. Her fourth delivery was somewhat over a year past and was followed by leakage of urine for which two operations had already been undertaken without success by the vaginal route.

The note of operation which was undertaken on the second of November 1929 is as follows:

Owing to several misadventures primarily associated with pregnancy (for the details of which see previous history) this patient now presents (1) stones in the bladder, (2) a high vesicovaginal fistula, (3) an irregularly split and scarred uterine cervix, the exact canal of which it has been impossible to locate. Satisfactory cystoscopy has been impossible on account of the painful condition of the bladder because of the stones, so that the exact relation of these pathological conditions to the ureteral orifices is not known. For this reason, as well as because of the high position of the fistula, it seems that it had best be approached by the superior route.

An incision was therefore made above the pubes incising the scar of previous operation and opening the bladder. From the bladder were extracted two stones after which there was found to be a definite deformity of its floor. An irregular band of tissue ran from the approximate region of the interureteral bar upward for a distance of about 1½ cm. This was cut across and below it there was found to be the orifice of the fistula into the vagina. The right ureteral orifice was found below this but because of the chronic granulation tissue probably caused by the stones the left ureteral orifice could not be identified. The problem of separating the bladder from the vagina was then approached. The bladder was freed from the peritoneum over its vault, and from the anterior surface of the uterus. On reaching the region of the cervix dense scar was found which could not be separated except by sharp dissection. In order to reach this area for farther dissection better exposure was necessary so that the posterior wall of the bladder was incised in the mid-

*From the Urological Clinic of the Peter Bent Brigham Hospital, Boston, Mass.

†Quinby, William C.—Clinical Professor of Gynecology and Surgery, Harvard University Medical School. For record and address of author see The Week's Issue, page 426.

line and this, together with the incision previously made in the anterior wall, divided the whole detrusor portion of the bladder into two lateral halves. Comfortable access to the floor of the bladder and anterior wall of the cervix was thus obtained, and eventually by sharp dissection it was possible to separate the bladder from the cervix and from the anterior vaginal wall over an extent sufficient to allow the wound in the bladder to be turned inward and closed by suture. During this dissection, care was taken to stay as near as possible to the mid-

line, because of the fact that the exact course of neither ureter was known. One or two sutures were also placed in the anterior vaginal wall in an attempt to unite this, but the approximation here was not good. The two halves of the bladder were then united by interrupted sutures upward as far as the vault, and drains placed both inside and outside the bladder. The vagina was also drained by a cigarette wick."

The patient's convalescence was uneventful and she was discharged well on the twenty eighth day after operation. Six months later the patient wrote that she was entirely well.

From this experience one can fairly draw several conclusions. First, as regards the approach by the suprapubic route the indications were clear because of the extensive vaginal scarring and contraction which evidently followed the previous operation by the vaginal route. In view of the aberrant band of intravesical tissue seen as soon as the bladder was opened no closure could have been successful until this was removed, a procedure which would have been quite impossible by the vaginal approach. Secondly, complete mobilization of the floor of the bladder from the adherent underlying vagina is always necessary before the bladder can be closed without tension. In order to achieve this, the bladder was split into halves. Due to the fact that its blood supply comes mainly from the lateral vesical arteries, healing followed without interruption. The increased accessibility of the area of the fistula thus gained was of the greatest aid. Thirdly, if the bladder is closed accurately and without tension, the vaginal wall will heal satisfactorily by granulation

even though the approximation of the edges of its wound cannot be carried out perfectly.

These two cases illustrate sufficiently the problem of vesicovaginal fistula as seen by the urologist today. Those cases of fistula due to accidents of childbirth are fortunately not nearly so frequent as in the past. For the simplest of these the classic operation of Sims is still quite sufficient, although here no attempt is made to dissect the bladder away from the vagina. The edges of the fistula are merely refreshed and united by sutures which include both bladder wall and vagina. More commonly today fistulae are seen which follow previous operations such as total hysterectomy. Here the cervix has also been removed so that the fistula is very hard to reach by the vaginal route because of lack of anything on which to make traction. Other more complicated cases are seen as those in which the opening in the bladder communicates with the canal of the cervix or as those in which the ureter as well as the bladder has been injured with a resulting ureterovesicovaginal fistula. For all such instances it is my firm belief that the operation carried out from above is much more likely to be followed by cure than any attack by way of the vagina.

Other instances of vesical fistulae more recently seen are those in which the floor of the bladder has been caused to slough over a smaller or larger extent as a result of the application of radium for cancer of the uterine cervix. In such instances the resulting scar is usually very

dense and the loss of tissue of the bladder floor and vaginal vault extensive. In two such instances relief was obtained by implantation of the ureters into the sigmoid colon, thus abandoning the bladder entirely as a functioning organ.

Our experience with the treatment of cases of vesicovaginal fistula leads us to the following conclusions:

The object of operation for vesicovaginal fistula is to get a tight bladder the bladder must hold urine, the vagina cannot

Closure of the bladder should be as perfect as possible closure of the vagina is an entirely secondary consideration, it need not be perfect for it will heal by granulation

The easiest and most complete access to the bladder is by the suprapubic route and this should be employed in all but the simplest cases.

Sufficient mobilization of the floor of the bladder from the vagina is imperative. If necessary this can be much facilitated by splitting the whole detrusor portion of the bladder in a sagittal direction

Opening the peritoneal cavity during operation is not dangerous if the subsequent repair of the bladder is perfect.

After operation the bladder should always be kept in complete rest by constant drainage until healing has taken place

Serious and extensive loss of bladder tissue with dislocation of the ureters and much scarring is in most instances best treated by bilateral ureterosigmoidostomy

DISCUSSION

DR. JOHN HOMANS Boston Mass. I would like to ask Dr. Quinby a question which he may or may not thank me for I do not feel quite clear in my mind as to whether he begins by going into the peritoneal cavity at all. One would suppose the approach would always be easier from outside the bladder and indeed he showed in one of his pictures an approach behind the bladder and between the bladder and the uterus. He speaks first, however as if he had entered only the bladder itself.

I ask this question partly because I have just closed a rectovaginal fistula very high and inaccessibly, through the abdominal cavity with comparative ease, although there was a tremendous amount of scar tissue, owing to a large foreign body which had sloughed out. It was not at all difficult to close the rectal wall from inside the pelvis and I should think the same thing would apply to the bladder

DR. J. D. BARNES Boston Mass. I am very much interested in what Dr. Quinby had to say about vesicovaginal fistula. I have nothing to add except I agree thoroughly with all his ideas about the importance and real necessity of going at these things from above. It has been my experience that the

repair of the vaginal defect is by no means so important as I was always led to suppose. If the defect in the bladder is repaired I think the injury to the vagina will generally take care of itself

As a matter of fact, I found it very difficult in a great many cases to do anything about the repair of the vaginal aspect of the fistula, because it is so high up in a cone-shaped cavity one cannot see it well much less work on it. That is particularly true I think, where the uterus has been previously taken out.

The last two cases I have had within a year were in women who had had hysterectomy. They came from the same district and were done by the same surgeon. Both resulted in fistulae through which one could easily put the thumb right at the junction of the bladder and vaginal wall. The scar tissue was such that there was a tight ring as it were

I did them from above and found in my desperation in the doing of the second case, that I was much aided by the use of the tonsil knife, which has the blade at right angles to the shaft. There is a right handed and a left handed one.

I found working in that deep hole, that I could put these down one this way and one the other way and undermine the mucosa for a considerable distance around the fistula. By careful use of the knife, I could also separate the bladder wall from the vaginal wall.

I have never used it before and do not know whether it is an original idea but I suggest it for just what it may be worth.

PRESIDENT JOHNSON Is there any further discussion? If not, Dr. Quinby will you close the discussion?

DR. QUINBY Do I quite get your question Dr. Homans, in regard to the peritoneum? I simply mentioned the peritoneum to go on record as stating that it makes no difference whether the operation is done via the peritoneal cavity or not.

As a rule, one does not open the peritoneal cavity. One does almost always open the bladder but sometimes it is possible to dissect the bladder away from the anterior vaginal wall without opening the bladder. In that case one is in front of the peritoneum, between the bladder and the uterus assuming that one is left.

DR. JOHN HOMANS It was my idea to ask you whether you objected to that route. It would seem to me to be preferred.

DR. QUINBY Splendid only very frequently one opens the bladder first which usually does not necessitate entering the peritoneal cavity. According to what one finds and the room one needs the peritoneum is either opened subsequently or not as the case may be. It makes no difference. As you say it is frequently much easier to do it that way.

Does that answer your question?

DR. HOMANS Yes.

is to remove pleural fluid in patients with circulatory failure as soon as any considerable dullness is detected in the percussion of the chest. As a rule, with hospital patients this is done along with the institution of bed rest and digitalis on the day of admission, followed by 15 mgm (1/4 grain) of morphia sulphate at bed time as the most effective way of managing such patients. Ascites and subcutaneous edema on the other hand, in this type of patient with few exceptions respond well to the proper diuretics and do not need mechanical removal. When they do not, mechanical drainage of both should be resorted to.

Some types of cardiac disease are much more apt to show extensive general anasarca than others. The patient with chronic nonvalvular heart disease, with or without hypertension, oftenest with regular rhythm but at times with auricular fibrillation, is the type of cardiac disease in which oftenest we see marked edema and such patients frequently respond to diuretics with a truly remarkable outpouring of fluid, which in eight to ten days will reduce the patient's weight by from twenty to sixty or even more pounds. This therapeutic response may be obtained over and over again in such patients.

If such a patient is given adequate digitalis with fluid intake restricted to 800 or 1000 cc for from three to five days, there may be a marked diuresis as the result. Usually however, the edema remains marked after this period of digitalis, and now diuretics will be strikingly effective.

In these patients often the xanthine diuretics are very effective. These have the advantage of being effective by mouth dosage and so more convenient to give and more comfortable for the patient to take. In my experience of these theocin (theophyllin) is most effective. The best way to give this diuretic is in two doses of 0.3 to 0.5 Gm ($4\frac{1}{2}$ to $7\frac{1}{2}$ grains) with half a glassful of water at 7 and 10 A.M. If a diuretic is given early in the morning, the active diuresis will come during the patient's waking hours and not interfere with the night's sleep. An interval of forty-eight to seventy-two hours between the administration of diuretic drugs is preferable, although at times daily dosage is advantageous. These last two statements apply both to the xanthine and mercurial diuretics.

If xanthine diuretics fail to give good results mercurial diuretics should be given. They almost always are more effective but have the disadvantage of requiring dosage by a parenteral route preferably the intravenous route though intramuscular dosage may be entirely satisfactory. Either route will give a good diuretic response but often intramuscular dosage may cause irritation and hence discomfort. Subcutaneous dosage with mercurial diuretics

almost always is too irritating to be used and at times causes necrosis and sloughing of the skin.

There are now generally available three mercurial diuretics, novasurol (merbaphen), salyrgan (mersaly) and mercurpurin. Of these novasurol is the most likely to cause toxic symptoms while salyrgan and mercurpurin, though containing more mercury, are less toxic. I have the impression too that salyrgan and mercurpurin cause a greater diuresis than does novasurol. In my experience salyrgan and mercurpurin are equally effective as diuretics and there is no difference in irritating qualities between the two when given intramuscularly.

All of these three mercurial diuretics have a further disadvantage in that their maximum activity is when the reaction of the blood and probably of the tissue fluids is shifted toward the acid side. This entails preceding by forty-eight to seventy-two hours the administration of the mercurial diuretic by quite large doses of acid salts such as ammonium chloride 2 to 4 grams (60 to 120 grains), three or four times a day. Recent studies in the laboratory of the Department of Medicine at Harvard by Dr. Marshall N. Fulton and his associates have shown that this is clearly a relationship to the shift toward the acid side and not related to the ingestion of the chloride ion.

Very recently a definite advance has been made in that a mercurial diuretic has been prepared by the Campbell Products, Inc., which is very satisfactorily effective when given by rectum in the form of a suppository. This is the highly complex organic mercury compound which is present in mercurpurin there combined with a xanthine substance. This obviates the necessity of intravenous or intramuscular dosage for mercurial diuretics, but still requires the preliminary days on ammonium chloride.

These mercurial diuretics are dispensed in sterile form as a ten per cent solution of the drug, and the dose is 1 to 2 cc. of this ten per cent solution to be given the first thing in the morning and repeated if necessary, on the third or fourth day so long as considerable edema persists. The dose in suppository form is five times the dose for intravenous or intramuscular use. Experience shows that this treatment may be kept up for months with no bad effects.

As some are said to be very sensitive to mercurials, it is a common practice to give first a test dose of $\frac{1}{2}$ cc. one or two days before giving the larger dose. This has always been our practice at the Peter Bent Brigham Hospital but I can recall no instance of the detection of undue sensitivity to the mercurial.

Actually it is very rare to see any toxic action from mercurial diuretics given as described above, certainly this is true for salyrgan and mercurpurin which we have used to the exclu-

sion of novasurol ever since each of these was sent to us for trial prior to being put on general sale. This seems an unexpected result, when you recall that mercury often causes toxic disturbances, stomatitis, colitis, proctitis, nephritis, and that in many patients with edema there is a coincident or causative renal lesion, either chronic passive congestion or nephritis. Furthermore in normal animals these mercurials regularly cause albuminuria. The fact, however, remains that in proper therapeutic use, we are rarely, if at all, disturbed by the development of manifestations of toxicity.

In the ascites caused by cirrhosis of the liver the xanthine diuretics in my experience have been ineffective. The mercurial diuretics, used as described above, quite often cause a considerable diuresis, but unfortunately it is rare for their effectiveness to be sufficient to control the ascites, and mechanical removal must be resorted to. The use of the mercurial diuretics in patients with cirrhosis of the liver may serve at times to prolong the interval between necessary taps of the abdomen and so they should be used. However, at the Peter Bent Brigham Hospital, as shown in a recent study by Dr. Marshall N. Fulton of thirty-seven patients, the results of the use of mercurial diuretics in patients with cirrhosis of the liver were disappointing, the response to mercurial diuretics in cirrhosis of the liver is almost always very much less than in patients with either edema of cardiac insufficiency or the nephrosis type of renal edema. In an occasional patient with ascites from cirrhosis of the liver, I have seen a good diuresis from large doses of urea.

In edema of renal origin, the nephrosis syndrome, the xanthine diuretics have almost no effectiveness. The mercurial diuretics, however, used as already described, may produce a very marked diuresis. Fortunately they do not injure the kidney in this form of renal disease and so may be used repeatedly with entire safety. In those forms of nephritis in which there is marked nitrogen retention mercurial diuretics should not be used.

Certain patients with this nephrosis form of edema, however, are not responsive to the mercurial diuretics. Occasionally for them large doses of urea, 60 to 90 grains per day, may give a good diuresis. Urea is not to be used when there is already an existing nitrogen retention.

Urea failing to give diuresis, this type of edema may be treated satisfactorily by intravenous injections of fifteen per cent solution of gum acacia, in amounts from 400 to 500 cc. Recently gum acacia has been available in satisfactory purity so that these intravenous injections may be given without disturbing reactions. The principle on which the acacia works is to raise the osmotic pressure of the blood, the lowered osmotic pressure from the deficiency

in plasma albumin in this type of edema being the chief causative factor in causing the edema. This form of treatment, of course, is applicable to any form of edema due to lowered osmotic pressure in the circulating blood.

In recent years there has been much investigation of the mechanism of activity of diuretics. One view, formerly held, that diuretics acted chiefly extrarenally, that is by producing changes in the tissue fluids that caused an increased drainage into the blood stream with resultant increased excretion by the kidney, has largely been given up. The great majority of investigators now consider that the xanthine and mercurial diuretics both have a direct action on the kidneys.

The two ways in which a diuretic drug might be expected to work are (1) increased glomerular filtration and (2) decreased tubular reabsorption. We have no satisfactory way of determining the activity of these mechanisms. The Rehberg formula, based on creatinin excretion taking place only through the glomerulus, is not well supported by recent studies. Its application has led to the view that the xanthine diuretics act chiefly by increasing glomerular filtration and the mercurial ones by decreasing tubular reabsorption. Possibly this difference in action may exist. Certain it is that normal urine excretion depends on a proper balance between glomerular filtration and tubular reabsorption. How great tubular reabsorption is under normal conditions of urine formation is not generally realized. According to Cushing in order to form one liter of urine, sixty-two liters of water are filtered through the glomeruli, sixty-one liters of which is reabsorbed in the tubules. Obviously not much retardation of this tubular absorption would be required to increase an average 1,000 cc urine flow to 5,000 cc or to 6,000 cc, which would be regarded as a very good diuretic effect.

SUMMARY

A schema showing the various types of edema is presented. Clinically edema should be regarded from two angles, (1) as an index or sign of pathologic disturbances and their progression and (2) as a cause of discomfort and disability to the patient. Edema causing no discomfort or disability needs no special treatment.

Circulatory and renal edema, as a rule, are the types requiring special therapy.

In cardiac circulatory edema, hydrothorax should be removed early by thoracentesis, edema elsewhere, if persisting after proper digitalis therapy, should be treated with diuretics. Xanthine diuretics often are effective, they have the advantage of mouth dosage and require no preliminary drug other than digitalis. These failing, mercurial diuretics are available, they

require preliminary treatment with ammonium chloride and are effective only when given parenterally, intravenously or intramuscularly. Recently one has been discovered effective by rectum.

In ascites from portal obstruction xanthine diuretics are ineffective, mercurials produce a diuresis but rarely great enough to obviate paracentesis of the abdomen.

In renal edema xanthine diuretics cause very little diuresis, while mercurials usually are effective and do not cause renal damage. Mercurials failing to be effective, intravenous injections of acacia solutions may cause effective diuresis.

In all of these conditions urea, in very large doses, may be effective. All diuretics should be given in the early morning hours and at intervals of forty eight to seventy two hours. The xanthine and mercurial diuretics seem to act directly on the kidney.

DISCUSSION

Dr. BURRICK. I wish to congratulate the Society on being privileged to hear so able a presentation. I think if the members will take this material home with them they can do their edematous patients a lot of good.

Dr. HILL. I would like to ask Dr. Christian's opinion of the Niemeyer pill which when I was in college fifty years ago was lauded beyond any question.

Dr. CHRISTIAN. The Niemeyer pill is like many older preparations that fall into disuse because they are complex and because it was difficult to use them to give the necessary variation in the case of each constituent. Some of these old preparations are very effective, but you can fill your individual patients' needs with therapeutic doses if you give the ingredients separately. We have made great progress in these newer synthetic combinations and they practically replace a lot of the so-called galenicals.

MISCELLANY

VERMONT DEPARTMENT OF PUBLIC HEALTH

JANUARY 1936

The following communicable diseases were reported to the office of the Department of Public Health during the month of January: chickenpox 3, diphtheria 2, smallpox 1, measles 689, German measles 64, mumps 177, typhoid fever 1, poliomyelitis 2, scarlet fever 68, whooping cough 166 and tuberculosis 8.

The Laboratory of Hygiene made 2,395 examinations the details of which are as follows:

Examinations for diphtheria bacilli	694
" Widal reaction for typhoid fever	36
" undulant fever	59
" gonococci in pus	133
" tubercle bacilli	201
" syphilis	678
of water chemical and bacteriological	31
" water bacteriological	187
" milk market	229
" milk submitted for chemical only	5
" milk submitted for microbiological only	58
" foods	3
" drugs	0
" for courts autopsies	0
" courts miscellaneous	11
" miscellaneous	69
Autopsies to complete death returns	1

The Director of the Division of Venereal Diseases reports thirty-nine cases of gonorrhea and forty-four cases of syphilis made to this Division in January. Eight hundred and fifty Wassermann outfits and 384 slides for gonorrhea were distributed from this Division.

The After-Care Nurses of the Infantile Paralysis After-Care Division made forty-two home visits calling on forty-six patients. Three patients were admitted to the Anduhon Hospital and one discharged from that hospital. Five patients were discharged from the Children's Hospital. Eighteen new pieces of apparatus were fitted, two pieces were altered and sixteen orthopedic corrections were made to shoes. The Vocational Worker of this Division reports sales made amounting to \$129.52.

Four towns of the state were visited by the State Advisory Nurse of the Public Health Nursing Division. The first half of the month was devoted to drawing up the budget and planning the proposed Social Security projects. The WPA State Nursing Project is increasing. There are now twenty-eight staff nurses, two supervisory nurses, one dental hygienist and two stenographers. Seven hundred and fifty-five notifications of birth registration were sent out in January, also 241 baby booklets.

HARTFORD MEDICAL SOCIETY

PRESIDENTIAL ADDRESS*

BY PATRICK F. MCPARTLAND, M.D.†

I HAVE listened to the retiring address of every president since I first became a member of this society. These addresses have awakened various reactions, generally a feeling of satisfaction but occasionally a small degree of disappointment so that I will not feel entirely abashed if my short address does not meet with your entire approval. We have had a number of meetings devoted to a discussion of economic problems during the past year and whether any advantage was gained from them I do not know. It may be that they will prove ultimately to have had some educational value which we as yet cannot fully estimate.

During the past year I have heard the opinion frequently expressed by many members of this Society that, with a return to normal conditions, all talk of these various economic problems would disappear and they would soon be forgotten. I certainly trust and anticipate that that forecast of the probabilities will prove unfounded. This is a conservative medical body, in a conservative city, in a conservative state, and changes are brought about with the utmost difficulties accompanied by many disappointments. It requires no prophet nor need one be possessed of an analytical mind, to foresee that we are at present wholly inadequately organized in our city, county and state societies to cope with medical problems as befits our position in the community either to advance or even protect our own interests.

Conditions in the medical profession are somewhat better than they were three years ago and in the opinion of many competent authorities it may confidently be expected that they will continue to improve for the next three or four years. Practically all economists agree that the standards of living in this country will decline for the next few years. Secondly, almost all students of world politics agree that we shall have a marked extension of all forms of social service legislation during the coming years. Thirdly, the most superficial observer can readily grasp the fact that organization of all industry and workers is proceeding at a rapid pace. These three facts are readily apparent to the most cursory student of economics. It is also self-evident that it is impossible to have any form of extension of social service or social security without vitally or at least seriously affecting the medical profession, regardless of whether it is unemployment insurance, old-age pensions, maternity aid, health insurance or any

other of the many forms. Social extension and medical involvement are synonymous. Hence, if organization of industry with all its ramifications is the watchword and social extension one of the ultimate fruits of that organization, then it seems to me that organization of the medical profession should become a paramount issue with us.

It is true that we now have an organization, but not an organization that has any material control over its members, or that has an authoritative representative qualified to express an opinion on any medical subject, or that could do business with any other organization and hope to adjust itself to circumstances that might arise and yet remain conscious of the support of the organization. Efficient organizations cannot be built in one day or overnight when we are confronted by some issue which may be of tremendous importance to our future and which has aroused the interest of every member.

This address then will be restricted to a few suggestions for a change or changes which I personally feel would be of inestimable advantage to the Society, yet I fully appreciate that at first thought scarcely any member of the Society may agree with me. However, I do hope that I will get a sufficient number of individual reactions and expressions of opinions, both favorable and unfavorable, so that it or they may be modified to a satisfactory and acceptable degree.

Let us consider the Board of Censors. According to our By-Laws the principles of medical ethics adopted by the American Medical Association shall govern our conduct. Subsequent to one of the recent regular meetings I inquired of eight members if they had ever read the Code of Ethics and of the eight, one stated that he had so done. One of the eight had seen service as a member of the Board of Censors of one of our medical societies. However, he was not the one who had read it. This is related merely as a passing incident. The Board of Censors is friendly to and with all of our members and to institute action against any member becomes a very disagreeable, difficult, and at times might well prove to be an almost insurmountable act. Hence, action is seldom instituted.

Let us assume that the president of any local hospital should violate the rule concerning unwarranted professional publicity and had obtained considerable desirable or undesirable publicity, according to the point of view. Further assume that the Chairman of the Board of Censors is a member of the same hospital staff. In

*Presented at the Annual Meeting of the Hartford Medical Society, January 6, 1936, by the retiring President.

†McPartland, Patrick F. — Attending Surgeon, St. Francis Hospital, Hartford, Conn. For record and address of author see This Week's Issue, page 436.

that event is there any member so naïve as to expect that any action would be taken by the Board? No, that is too much to expect. Now I like publicity as much as anyone and appreciate it at its full value. I have also had sufficient experience with newspapers to realize that practically all publicity is with the approval if not the instigation, of the professional beneficiary.

Again let me clarify the situation by stating that it is not my intention to direct thoughts toward past conditions. I am thinking wholly of the future. You might well answer that no president of any local hospital could be guilty or permit such an incident to occur to which I reply that no condition should be permitted to continue to exist where he or anyone else could permit it without full realization that he would be obliged to explain it promptly and, more to the point, satisfactorily to the Board of Censors.

During the period of my membership in the Society, if my memory serves me well, but one member has been expelled from this Society. As I recall it three other members were recommended for expulsion but because of legal entanglement no one of these three was expelled. Actually it is practically impossible to expel a member and who of you can recall any member who ever received any sort of punishment? Fortunately the circumstance rarely arises where such action is necessary or has to be considered but to my mind that makes it all the more imperative to have some means to carry out the desires of the Society when the occasion requires it.

Here is where the Bolshevik within me asserts itself and I suppose where we all part company. First, let all complaints having to do with violations of ethical conduct be referred to the Clerk of the Society. Secondly let her arrange the time of meeting after communicating with the Chairman of the Board of Censors and with the accused. Thirdly, let all actions of the Board of Censors involving ethical conduct be reported at the next meeting of the State Medical Society following the completion of the hearings. Let the action of the Board be final but reversible by a two-thirds vote the report being one for information including the name of the member involved. Fourthly with all applications for membership let the applicant fill out at the same time his or her prospective resignation from the Society at the pleasure of the Board of Censors for just cause. This blank shall contain an explanatory legend informing the applicant of his rights. Fifthly if adopted ask each present member to sign voluntarily his or her resignation under the same conditions.

To recapitulate a method is suggested that will remove initiative for violations of ethical principles from the Board of Censors and place

it where such reports will be invited. Secondly, a provision is made for publicity within the Society for accused members. Thirdly a method is suggested that will permit the Society to terminate the membership of undesirable members. A possible criticism is that the Board if composed of one group of which the accused was not a member, would accept his resignation but the two-thirds rule would protect him and anyway I think that the reasoning is absurd.

Another criticism is, how can a member resign before he is elected? He cannot. But I am informed that the phrasing of the application can be formed to cover these objections. In any event it is my hope that enough suggestions can be offered both in favor of and against so that it may be made acceptable. I will frankly state that I have no motive except to correct one of the weaknesses of our present By Laws.

Another method that could be adopted which would be simpler and probably one that would not provoke the same element of controversy would be to have each applicant for membership in the Society sign a waiver to his right in the Trust Funds of the Society providing the Society found it necessary to terminate his membership with the organization for just cause. In any event some method should be adopted not because there is any immediate necessity for it but to protect the Society in the future.

Our Economics Committee is assumed to have some direction over practices of the members in relation to each other or in groups, or with corporations. They are supposed to keep the Society informed as to various activities of these groups. Sometime within the past two years a group of specialists within the Society, after several meetings, agreed on prices and other conditions pertaining to their particular line of work. It seems to me that practices of this kind should be reported to the Economics Committee and so placed on record. This applies as well to the Hospital groups which have agreed to pool all funds received from certain types of patients and to divide them equally among all participants. I do not mean to imply that there is anything wrong with the practices referred to. Nevertheless, I cannot help but feel that for the best interests of all concerned such arrangement should be placed on record. It may be that the next group to adopt similar practices founded on those previously put into operation will have been sufficiently changed in their construction and operation to make them questionable.

Another change which it appears to me might well be adopted during the coming year is the appointment of a Hospital Committee. This committee should consist of members associated with each of the various hospitals in the city. It might well make an effort to have adopted by each of the local hospitals an agreement which would permit only those approved by the

Medical Society to practice in such hospitals. This could be brought about by having all applications for courtesy staff privileges in the various hospitals referred to this committee. The findings of this committee to be adopted by all hospitals and the privileges allotted then to become uniform. This would apply to all, whether they were members of any society or not. Secondly, an agreement that when the society withdrew privileges from any doctor the hospitals should do likewise. This committee might well consider an effort to have modified the marked variation between ward and semi-private patients. The \$15 difference is against the best interests of the private practitioner. The tonsil situation, and soon the maternity situation, could be given considerable attention by such a committee. Indeed, the whole question of admission of patients and a proper amount of investigation by each of the various hospitals would result in much benefit. My object is not to approach the hospitals with anything of a dictatorial attitude, but rather to attempt to cooperate with them and bring about some uniformity in many methods now in vogue, some of which are at the present time detrimental to the profession in general.

Of course many members will promptly dismiss these suggestions with disapproval and confess that nothing can be accomplished. It is also true that if we adopt that attitude nothing will be accomplished. However, practically everyone will admit that today the hospitals are actively competing with the individual doctors and it is only by organized effort to control or restrict them that it will be possible to accomplish any material change.

I believe that any move to improve the medical profession, either the conditions under which we operate, or the character and quality of the work that we do, yes, even to modify the sentiment of the community toward the profession, either individually or collectively, is worthy of our attention. It is because of this belief that I am referring to the supposedly drunken automobile driver. On numerous occasions during the past year the newspapers have referred to cases where two doctors examining a supposedly drunken automobile driver in from ten to thirty minutes of each other have produced sworn testimony diametrically opposed. The frequent repetition of these instances is decidedly antagonistic to the best interests of our profession and any effort which we can contribute to the solution of this problem would produce an equally favorable reaction. The suggestion has been made that the Society go on record as recommending that two doctors be required to examine all individuals suspected of this condition. Before doing so it would appear to be the part of wisdom to have either the Economics Committee or the Board of Censors consider the entire question.

I appreciate the fact that this entire paper will seem to many to be an unusual one to bring before our Society at this time. However, conditions over which we have no apparent control are also unusual as well as the outlook for our future. It is because of these facts and with the hope that some discussion may be stimulated among our members that it has been presented to you as the final gesture of my one year of a pleasant, instructive experience. I thank you.

AFFAIRS IN CONNECTICUT

(Continued from Page 414)

approached in such instances instead of making sweeping accusations against the whole profession.

"We would call attention to the very uncomfortable situation in which a family physician finds himself when he is asked to testify 'on behalf' of one of his patients, and we believe that our members, whenever it is possible, should disqualify themselves from giving testimony under such circumstances.

"We are very jealous of the good repute in which physicians, as a class, are held, and the Hartford County Medical Association will go to any reasonable length to curb such practices of its members as would impair that good repute. The authorities may rest assured of the fullest cooperation of the organized medical profession in stamping out any so-called 'rackets' if they are found to exist."

THE CLOSING OF THE CHARTER OAK HOSPITAL

On February 1, 1936, the Charter Oak Hospital in Hartford, Conn., closed its doors after twenty-nine years of service. Founded in 1907 by the late Miss Mary C. McGarry, the hospital specialized in the care of surgical patients. One of the first, if not the first, operation for removal of the thyroid gland was performed there in 1911 by the late Dr. O. C. Smith. This surgeon performed there one of the first prostatectomies in Connecticut. In this hospital in 1910, Dr. Henry C. Russ carried out one of the first Wassermann tests.

It is planned to conduct the Charter Oak Nurses' Club in the building formerly used as a hospital. In a statement to the local press Miss Mary Cummins, superintendent of the hospital, stated that "the decision to close the hospital was taken on the belief that no private hospital could survive in modern times without an endowment fund."

CASE 22091

PRESENTATION OF CASE

A fifty-nine year old Hebrew physician entered complaining of pain in the lower back.

About five months prior to admission the patient developed, rather rapidly, dull aching pain in the lower back, more marked on the left side. The pain radiated into the left flank and hip became progressively worse, and was marked by frequent sharp exacerbations. Approximately two months after the onset of his illness he began to suffer from periods of apathy and somnolence during which he appeared confused and disoriented. There was some increase in urinary frequency and occasional incontinence. His appetite became quite poor. He was subsequently admitted to a hospital where traction was applied to the left hip with some relief of his pain. He also received therapeutic doses of bacteriophage. While in the hospital he was observed to have paroxysmal attacks of auricular fibrillation occasionally with rather slow rate. During one of these episodes his apical rate was found to be 36. The blood pressure was 135-80/75. Examination of the blood showed a red cell count of 3,500,000 with a hemoglobin of 70 per cent. The white cell count was normal. A blood urea nitrogen was 30 milligrams per cent. Electrocardiograms at times showed normal rhythm and at other times absolute arrhythmia. The T waves were considered significant of myocardial damage and there was left ventricular predominance. The blood calcium was 16.5 to 16.8 milligrams per cent, the phosphorus 3.2 milligrams per cent. The serum protein was 5.6 grams per cent, of which the albumin was 4.3 and the globulin 1.24. He showed a well-defined negative calcium halance. Eleven days prior to entry he was referred to another hospital where further studies were made. A phenolsulphonephthalein test showed 10 per cent excretion in two hours. A blood calcium was 14.6 milligrams the phosphorus 6.0 and the phosphatase 0.51 K units. Examination for Bence-Jones protein was negative. The nonprotein nitrogen of the blood was 75 milligrams. The total protein was 7.4

grams per cent. X-ray examination showed moderate decalcification of the lumbar vertebrae, pelvis, sternum and ribs. The lungs were clear except for a few areas of fibrosis in the left apex. The skull contained multiple small, clear out areas of decreased density. There was no evidence of increased intracranial pressure. A later film showed destruction of the first lumbar vertebra with collapse of its body. Films of the bones of the upper and lower extremities showed no decalcification or mottling. At the end of a week he was referred to this hospital for exploration for a parathyroid tumor.

Twenty-one years prior to entry the patient began to suffer attacks of precordial pain which were precipitated by exertion. These attacks occurred at fairly frequent intervals for six years, at the end of which time a thyroidectomy was done with subsequent relief. The pathological report was said to have been "mildly toxic thyroid adenoma." Ten years before admission a left nephrectomy was done for hypernephroma. Following this he received an intensive course of x-ray treatment. A vague story was obtained of his having suffered from both pneumonia and rheumatic fever in childhood.

Physical examination showed a slightly undernourished man who, though somewhat somnolent, responded well to questioning. He complained of pain in his back. The left pupil was slightly larger than the right. They both reacted to light. Ocular movements were normal and the fundi showed nothing of significance. The apex impulse of the heart was not felt. The left border of dullness was 12.5 centimeters from the midsternal line in the fifth interspace. The right border of dullness was 4.5 centimeters to the right of the midsternum. The supracardiac dullness was 4 centimeters. The sounds were forceful and of good quality, and the action was regular. Heard over most of the precordium but loudest at the apex were a soft, early systolic, blowing murmur and a rather loud blowing early to middiastolic murmur. There was no transmission toward the axilla. The sounds were heard best over the neck vessels. No thrills were felt. There was tenderness over the left sacroiliac joint and also bilateral costovertebral tenderness. The tendon reflexes were normal and no Babinski sign was elicited.

The temperature, pulse, and respirations were normal.

Examination of the blood showed a red cell count of 3,000,000, with a hemoglobin of 55 per cent. The white cell count was 7,000. 80 per cent polymorphonuclears. The urine showed a slight trace of albumin. The sediment contained occasional white blood cells and one to four red blood cells. The blood calcium was 15.6 and the phosphorus 3.64. The serum protein was 5.5. The nonprotein nitrogen of the blood was 82 milligrams per cent.

Shortly after entry operation was performed. The patient responded poorly, went downhill rapidly and died quietly on the fifteenth hospital day, eleven days postoperatively.

DIFFERENTIAL DIAGNOSIS

DR WALTER BAUER Will Dr Hampton show the x-rays? The points that will be of most interest to us are (1) Are the observed areas of bone destruction consistent with metastatic malignant disease? (2) Does the skull show any decalcification in addition to the punched-out areas?

DR AUBREY O HAMPTON No, the skull does not show any diffuse decalcification. It shows sharply localized round areas of bone destruction varying in size from a millimeter up to a centimeter. They are separated by as much as two or three centimeters, not so close together as one would expect in diffuse decalcification. He has some changes in his ribs, not so well seen. There is a small round hole in a rib on the left and one there on the right which is not very distinct. He does have a little deformity of his chest, a Harrison groove, the type of thing he might have had all his life or may have developed in this disease. I do not see any pathologic fractures of the ribs.

The lung fields are clear as described and I cannot see much wrong with the heart in a portable film taken with the film at the back, such enlargement as is apparent is probably mostly magnification.

Here is the first lumbar vertebra, which is described as being definitely wedge-shaped. It is grossly irregular. In fact, you cannot see the anterior margin. It disappears as if it were destroyed. None of the other vertebrae show similar destruction or any bone deformity, but they do appear decalcified. The extremities as described are absolutely normal, no decalcification. There is calcification in the blood vessels, but not much. They look like perfectly normal extremities.

DR BAUER I think the x-ray findings are of considerable help in the discussion of this case. I would like first of all to discuss the findings concerning the heart and then come back to the real problem.

He might well have had rheumatic fever in childhood. If so, we have reason to believe that he developed rheumatic heart disease. The attacks of precordial pain always precipitated by exertion may have been due to angina pectoris, or may have represented attacks of either paroxysmal tachycardia or paroxysmal fibrillation. In all events it would appear that he had suffered from a mild thyrotoxicosis, which was in part responsible for the production of this particular symptom because it disappeared following the removal of what was interpreted as a mild toxic thyroid adenoma. If I interpret the

notes correctly the murmurs were transmitted to the neck, particularly the systolic murmur. If this was true I should be inclined to think that he probably had both aortic and mitral valve disease. He may well have developed subsequent calcification of his aortic valve which in turn may have been responsible for the heart block which was observed on at least one occasion. I do know that associated with calcification of the aortic valve one does observe recurrent attacks of Adams-Stokes syndrome. Therefore, I would interpret the cardiac findings as follows: rheumatic heart disease with aortic and mitral involvement and probably calcification of the aortic valve.

The only other thing in his past history which must be seriously considered is the note pertaining to the operation performed ten years prior to this admission. A left nephrectomy was done for a hypernephroma. As you can all see from the record, the final question to be answered is: Did this patient have hyperparathyroidism? He entered with a complaint, which in many cases is a very difficult one to interpret, that is, backache. As we go on we find that we have sufficient additional information to allow us to consider various leads. I do not know why traction was applied to the left hip. The hip at that time may have shown some hypertrophic changes. These changes may have been interpreted as the cause of his pain and in consequence traction was applied to afford relief. I do not know but I should imagine that traction was employed for some other disease state than the one he was finally suspected of having.

Did this man have hyperparathyroidism? When one suspects this disease one must always attempt to ascertain what symptoms are consistent with such a diagnosis. In going over this man's history one finds that he had none of the symptoms attributable to hypercalcemia, such as lassitude, weakness, constipation and others. There are no symptoms referable to an increased calcium excretion, such as polyuria, polydipsia, renal colic, passing of gravel, etc. The only symptom suggestive of hyperparathyroidism in this individual is the one referable to the skeletal system and this is pain. This lone finding should not necessarily disturb us or prevent us from considering the disease, hyperparathyroidism. The presenting symptoms in this disease are many and varied. We know that in certain instances the first symptom may be that of renal colic. Such individuals may have no skeletal symptoms, and the skeletal x-rays may show no evidence of decalcification, etc. In others the presenting symptom is referable to the bony skeleton. Such patients enter because of bone tumors, fractures or skeletal aches and pain. The latter may be not unlike that presented by this particular patient. Therefore, the history in this particular case

does not enable one to rule hyperparathyroidism in or out. All we can say is that he does not have the symptoms of classical hyperparathyroidism.

The next question is: How shall we interpret the Roentgen ray findings? We know that the x rays are described as showing moderate decalcification of the spine, pelvis and sternum. In addition the first lumbar vertebra appeared to be destroyed in part and had collapsed. The x rays of the skull revealed punched out areas without associated decalcification. We further see from the x rays that there was no demonstrable decalcification of the bones of either the upper or lower extremities. This localized type of decalcification (spine) is encountered in patients with a pituitary basophilic adenoma, adrenal tumors, senile osteoporosis, metastatic malignant disease or multiple myeloma. The x ray findings are more consistent with a diagnosis of metastatic malignant disease or multiple myeloma than hyperparathyroidism. In this instance the well-defined decalcification is limited to the vertebrae. There is little to suggest generalized decalcification. Therefore the x ray findings are anything but suggestive of hyperparathyroidism.

The serum calcium varied from 14.6 to 15.5 and the serum phosphorus from 3.2 to 6 milligrams per 100 cubic centimeters. The serum phosphatase was 51 units a figure which is at the upper limit of normal. In other words the patient had a hypercalcemia. The serum phosphorus was on the low side of the normal limit. Are these the findings of hyperparathyroidism or can they be explained on some other basis? If they are due to hyperparathyroidism the patient had developed one of the complications of the disease, namely, calcification of the kidney or nephrocalcinosis. Such renal complications allow for a hypercalcemia of this grade without an associated hypophosphatemia. If this individual had had nephrocalcinosis it should have been demonstrated on x ray examination. It was not. Therefore, I think it can be ruled out.

What other disease might give us these findings? In widespread metastatic malignant disease we obtain such chemical findings. Mason and Warren reported such a case several years ago. The patient had a serum calcium of 17.3 and phosphorus of 4.1. In such cases the serum calcium is high but the serum phosphorus is normal or increased. The x rays showed moderate decalcification. If this decalcification was due to hyperparathyroidism one would expect the serum phosphatase to have been definitely elevated. However there are exceptions. In individuals with mild hyperparathyroidism have a normal or only slightly elevated serum phosphatase. One must also appreciate the fact that individuals with marked hyperparathyroidism remaining on a high calcium intake will have a

high serum calcium, a low serum phosphorus, a normal serum phosphatase and very little x ray evidence of bone involvement. In other words the phosphatase tells one the degree and extent of bone involvement existing in patients with hyperparathyroidism. In this particular case the blood chemical findings do not allow one to make a diagnosis of hyperparathyroidism.

This man when first seen had an anemia as shown by a red cell count of 3,500,000. Later it fell to 3,000,000. Patients with hyperparathyroidism may develop anemia but only when marked bone changes are demonstrable, in other words the classical form of hyperparathyroidism. We know that the extensive fibrosis in such cases does interfere with hematopoiesis and in consequence hypochromic anemia and leukopenia result. In this case I think the anemia without marked decalcification etc., allows one to state it was not secondary to hyperparathyroidism. An anemia of this grade would speak for marked hyperparathyroidism. Thus we know he did not have.

This man had obvious evidence of kidney impairment as shown by two nonprotein nitrogens which were well above normal, 75 and 82 milligrams per 100 cubic centimeters. His urine had a slight trace of albumin. Evidently no casts were seen. He did have a few white blood cells and one to four red blood cells. If this man had had nephrocalcinosis casts should have been present. When present one should determine whether they do or do not contain calcium. He did not have kidney failure due to nephrocalcinosis of hyperparathyroidism.

I think that we can gather a fair amount of evidence which would allow one to doubt the diagnosis of hyperparathyroidism. In doing so one has to lean very heavily upon the x ray findings, although the blood chemical findings are also helpful. The most reasonable interpretation, I think, is some form of metastatic malignant disease. Such a diagnosis would best explain all that we are dealing with. In this instance we know that the man was operated upon some ten years previously for a hypernephroma. Therefore, rather than entertain a long list of possibilities it would seem better to stick to a diagnosis of metastatic hypernephroma. This would also explain the cerebral symptoms which were encountered in this particular individual. I know of no case of hyperparathyroidism seen in this clinic in which cerebral symptoms of this sort have been encountered. Therefore in summary I should say that we are dealing with an individual whose findings are best explained on the basis of widespread metastatic disease, in this instance the metastatic disease being hypernephroma. It was also the cause of his renal failure. In addition I think he had rheumatic heart disease with aortic and mitral valve involvement. There probably existed calcification

of the aortic valve. In view of the fact that the man had obvious renal insufficiency one might contend that he had in consequence developed secondary hyperparathyroidism. This only occurs in long-standing renal disease. We know this patient had a normal nonprotein nitrogen two months prior to his entry, therefore I should say that secondary hyperparathyroidism did not exist.

DR TRACY B MALLORY Dr Aub, will you tell us your opinion about this man?

DR JOSEPH C AUB I have seen the man, yet I think it is only fair to say that before I saw him I wrote to his doctor saying, as Dr Bauer did, that he most likely had a hypernephroma, on the basis of the fact that he did not have an elevated blood phosphate or characteristic x-rays. Incidentally, the nephrectomy was done thirteen years ago. The man took a very long trip and arrived here very ill. We looked all over his body for bone metastases that could be biopsied, but none could be found by x-ray. On the bare possibility that he might have hyperparathyroidism and because the remaining single kidney was very badly damaged, it seemed justifiable to attempt an operation for a curable disease, though none of us thought the diagnosis likely.

He had had a toxic goiter two years before and we thought his heart was fibrillating and that he had associated arteriosclerosis. He had an inadequate kidney, a single kidney. We thought he died of pneumonia.

CLINICAL DIAGNOSIS

Metastatic malignant disease

DR WALTER BAUER'S DIAGNOSES

Metastatic hypernephroma

Rheumatic heart disease — aortic and mitral stenosis

Chronic nephritis

ANATOMIC DIAGNOSES

Recurrent and metastatic renal cell carcinoma of the left kidney

Primary hypernephroma of the right kidney

Chronic vascular nephritis

Pulmonary edema, bilateral

Operative wound Parathyroid exploration

Operative scars Left hemithyroidectomy, left nephrectomy

Arteriosclerosis, marked coronary, slight aortic and cerebral

Prostatic hyperplasia

Mitral stenosis

PATHOLOGIC DISCUSSION

DR MALLORY I think Dr Aub has brought out a point which both he and Dr Churchill felt before the operation. This man had a

disease from which he was undoubtedly going to die unless something in the nature of a miracle could be done for him. There was a bare possibility that he might have hyperparathyroidism and as long as that was a possibility it seemed worthwhile to operate even though the hope of helping him seemed very slight.

We found at autopsy that he did have a recurrence of his hypernephroma in the area from which the kidney had been removed. It had also grown in the form of tumor thrombus into the renal vein and started up the vena cava, as these tumors so often do. It had invaded the vertebral column with destruction of the lumbar vertebrae. Two small metastases were found in the lungs and numerous minute foci in the bones. It is noteworthy that the punched-out areas in the skull proved to be not metastases but areas of bone absorption about blood vessels.

The opposite kidney proved very interesting. It showed a circumscribed tumor nodule about three centimeters in diameter. On microscopic examination this tumor is entirely different in appearance from the recurrent tumor on the left. The recurrent tumor is a wild highly malignant growth with no vacuolization of the cells, no longer recognizable as hypernephroma. The one in the right kidney is a very well differentiated, slowly growing, typical hypernephroma so that I think there is no question we are dealing with a second primary renal tumor, not a metastasis from the first one. The difference in type of the histologic picture on the two sides is sharp enough to make me feel I can be dogmatic about that.

At operation no parathyroid tumor was found, in fact no parathyroid tissue could be identified and we had no better success at autopsy. The man had had a previous thyroidectomy and the normal anatomical landmarks were obliterated which made it a pretty difficult job.

The heart showed mitral stenosis, but the aortic valve was negative. It was slightly hypertrophied. The remaining renal tissue in the right kidney amounted to about 200 grams after deducting the weight of the tumor. It showed a moderate grade of vascular nephritis.

CASE 22092

PRESENTATION OF CASE

First Admission A twenty-nine year old white American bank teller entered complaining of abdominal pain.

Four years prior to entry the patient began to have a "lumpy" sensation in the midpigastrium which usually came on several hours after meals. This discomfort was relieved by soda and occasionally by spontaneous emesis. About six months after onset a gastrointestinal series was said to be negative. An inguinal hernia which had recently appeared was repaired at

this time. Following this he was free from significant symptoms until ten months before entry when he suffered from occasional shaking chills which usually came on about one hour after meals, lasted for about an hour and a half and terminated spontaneously with a drenching sweat. These attacks were sufficiently severe to cause him to return to his home and go to bed. Vomiting sometimes produced complete relief. He had four such episodes at intervals of about two months none of them associated with actual abdominal discomfort. Nine weeks before entry he began to suffer from a sensation of generalized abdominal distention, occasionally more marked in the epigastrium which came on when he arose in the morning. This was relieved by the ingestion of a small breakfast but recurred shortly thereafter and usually persisted until he had eaten his evening meal. It frequently returned later in the evening and occasionally disturbed his sleep. Rarely did he feel nauseated or vomit during these attacks. His bowel movements which had previously been regular now became costive, requiring a daily cathartic. After six weeks they became quite watery and despite the cessation of cathartics continued so until admission. There was no mucus or blood present. Ten days before admission colicky pain appeared in the abdomen and the sensation of distention became much less evident. The pain was relieved by eructation or the passage of flatus. After about a week the pains became much more severe, recurred every five minutes, and persisted for about one minute.

Physical examination showed an emaciated pale young man. The skin was warm dry, scaly. The heart and lungs were normal. Other than the presence of hernial scars no other findings in the abdomen were noted. Rectal examination showed small hemorrhoidal tags. The finger nails were cyanotic and thought to be clubbed.

The temperature was 98°, the pulse 94. The respirations were 30.

Examination of the urine was negative. The blood showed a red cell count of 4,580,000 with a hemoglobin of 65 per cent. The white cell count was 5,950. 67 per cent polymorphonuclears. The stools were yellow partly formed and contained a large amount of mucus. There was no blood, parasites or ova present. Microscopic examination showed the presence of moderate amounts of starch and fat. A Hinton test was negative.

X-ray examination of the chest was negative except for areas of calcification in the lung roots. A Graham test showed the gallbladder to be normal. The urinary tract was normal. A barium enema showed the colon to be normal except for the cecum, which exhibited slight concavity of its inferior medial aspect. There was intermittent spasm of the cecum, and the

ileum did not fill. A gastrointestinal series was normal except for a twenty four hour retention of barium within the loops of what appeared to be the ileum. A large amount of gas was present in the same region. At the end of forty eight hours the small intestine had emptied.

On the third day a laparotomy was performed. A large amount of amber-colored fluid was found in the peritoneal cavity. A mass about the size of a billiard ball was palpated on the right rim of the pelvis, and the terminal eight inches of the ileum and the bladder were adherent to it. The small intestine appeared to be very much hypotrophied. A lateral anastomosis was made between the terminal ileum and the ascending colon. The patient responded well postoperatively and was discharged on the nineteenth hospital day.

Second Admission, four years later

Following his discharge from the hospital the patient had recurrence of the chills noted above but these gradually became less frequent. He often had rumbling sensations in both lower quadrants which recurred about twice a month. Seven weeks before reentry he was awakened in the middle of the night by the first chill he had had in two years. Induced vomiting consisted of a large amount of undigested food. This was followed by profuse perspiration and considerable relief. He felt rather listless for several days thereafter and then remained well until five days before admission, when he had a similar chill directly after a meal. There was no associated abdominal pain or abnormality of the stools. He had lost about seven pounds in one year, five of them during the preceding two weeks.

Physical examination showed the patient to be thin but in no apparent distress. The heart and lungs were normal. The blood pressure was 120/65. The abdomen was tympanitic and slightly spastic. The abdominal scars were well healed. Tenderness was elicited in the right lower quadrant.

The temperature, pulse and respirations were normal.

Examination of the blood showed a red cell count of 4,300,000 with a hemoglobin of 70 per cent. The white cell count was 11,500. 80 per cent polymorphonuclears. The stools were brown and liquid. There was no mucus or blood present.

A gastrointestinal series showed that the ileocolostomy was functioning well. The cecum was flattened and there was a small pressure defect at its apex near the site of the appendix. The terminal ileum no longer appeared to be obstructed. The appendix was not visualized.

On the fourth day a laparotomy was done. An indurated mass was found behind the cecum and the terminal ileum. The cecum was mobilized and an indurated adherent appendix was found lying behind it. This was removed.

and the area was drained. The patient had a moderately febrile postoperative course. The temperature varied between 98° and 101° for two and a half weeks. He was discharged afebrile on the twenty-sixth hospital day.

Third Admission, one year later

About ten days after leaving the hospital the region through which the abdominal drain had protruded became inflamed. It broke down and fecal material drained from it. It remained open for a short time and then closed spontaneously. Following this it opened spontaneously at irregular intervals, and occasionally had to be opened surgically to allow for drainage of accumulated feces. Each time drainage occurred he suffered chilly sensations, lassitude and malaise for several days thereafter, but there was no recurrence of his old symptoms.

Physical examination showed no change from that previously noted except for a small sinus wound from which a catheter protruded. This was surrounded by a moderately tender red, indurated area.

The temperature was 99.6°, the pulse 80. The respirations were 20.

Examination of the blood showed a white cell count of 11,000, 65 per cent polymorphonuclears, 12 lymphocytes, 13 monocytes, 10 eosinophils.

A barium enema showed a mass which lay behind the ascending colon opposite the drainage tube. The colon was spastic in this region and there was evidence of marked mucosal thickening. The ileum filled, evidently through the ileocolostomy stoma. The terminal portion of the ileum was not visualized.

A laparotomy was performed on the seventh day.

DIFFERENTIAL DIAGNOSIS

DR RICHARD H. MILLER: This is a long and detailed history and I shall not attempt to read it all but run over it briefly picking out the salient points.

Four years before entry there was a vague story of epigastric distress, not mentioned again, and I would assume that he probably had a duodenal ulcer, though one cannot be sure. It is not of particular significance, I think. Ten months before he came in he had the onset of shaking chills, followed by drenching sweats, occurring once in two weeks. Then the story changes.

"Nine weeks before entry he began to suffer from a sensation of generalized abdominal distention, occasionally more marked in the epigastrium, which came on when he arose in the morning, and usually persisted during the day." The onset of distention, constipation, diarrhea, and colicky pain would, to my mind, suggest some type of narrowing of the lumen of the colon. I should think it meant a partial ob-

struction. The constipation would suggest that and the diarrhea would not, I think, rule it out.

"The finger nails were cyanotic and thought to be clubbed." In this particular case I do not know exactly how to evaluate this and will pass it over for the moment.

We find a mild anemia probably of a normocytic and hypochromic variety and suggesting some deficiency.

The stool examination is not particularly helpful.

You will note that he had calcification of the lung roots, which means to me old and probably healed tuberculosis. He had a normal gall-bladder, and x-ray shows slight deformity of the cecum with some retention of barium which would probably mean that there is a lesion in or around the cecum causing obstruction at the ileocecal valve.

"A large amount of amber-colored fluid was found in the peritoneal cavity." This would mean either an irritation of the peritoneum with an outpouring of fluid, or some interference in the liver, and, ruling out the latter, one would assume that some process was taking place in the peritoneum that gave rise to an exudation.

"A mass about the size of a billiard ball was palpated on the right rim of the pelvis, and the terminal eight inches of the ileum and the bladder were adherent to it. The small intestine appeared to be very much hypertrophied." That means some process, as I said a moment ago, near or in the cecum giving rise to a certain amount of stasis in the ileum, and the hypertrophy of the small intestine can be accounted for in that way. Operation was performed at this time but inasmuch as this tumor of the region of the cecum recurs again in the history I will not stop to discuss it at this moment.

Four years later, having been pretty well, he appeared again and stated that seven weeks before entry he had another of these chills and after this vomited and had profuse perspiration. He was well for five days, when the same thing recurred. I find it difficult to explain these chills and drenching sweats occurring at such long intervals. I associate the diseases which result in chills and sweats with the frequent occurrence of these phenomena, perhaps every day or more often, and therefore I do not know exactly how to explain them, but I feel nevertheless that they are evidence of an infection somewhere in the body which has not manifested itself in any other particular way.

Physical examination is again negative with the exception of tenderness in the right lower quadrant.

I do not look on the laboratory findings as particularly significant or indicative.

Here again x ray shows flattening of the cecum but the terminal ileum was, as one would expect, no longer distended because it was emptying itself through the stoma.

I should be inclined to think that the appendix had nothing much to do with the process. I believe it is an infectious condition and it may conceivably have started in the appendix but I think that is not the primary source of the disease. A second operation was now performed the appendix removed and an unidentifiable mass discovered behind the cecum.

He again came back in a year five years after the first admission. The story is that the wound had broken open from time to time and discharged fecal matter. I should have thought that he would have had the malaise before the wound was opened rather than afterward.

The physical examination is not materially different from the other times, except that he had a slight temperature and a draining wound surrounded by a tender, red and indurated area.

The blood examination is interesting showing a white cell count of 11,000. The thing that strikes one is the 10 per cent of eosinophils. I will refer to that in a moment.

In order to arrive at a diagnosis in this case it seems to me that first, in the consideration of this tumor mass around the cecum, one must decide whether it is of a neoplastic nature or whether it is of infectious origin. I do not think it is neoplastic and in that term I include cancer, sarcoma, Hodgkin's type of lymphoblastoma and other tumors of lymphoid tissue. I do not think so because it seems to me that any type of new growth would have progressed in these five years so far that the patient would have had evidence of disease elsewhere in the body or what is more probable would have been dead. That brings me down to the decision that this is a tumor of infectious origin. What might that be? First of all, tuberculosis. Secondly syphilis and I am going to rule out syphilis because he has a negative blood test. Thirdly, a nonspecific infection resulting from the original disease in the appendix itself. I am going to rule that out because it is so rare and would be so extraordinary. The occurrence of ten per cent eosinophils makes one think of some parasitic disease and yet there is really no parasitic disease, which I can think of, that would ordinarily cause the picture as we see it here. Actinomycosis might account for the lesion as it occurs in this case, and yet it would be very unusual for actinomycosis to remain limited in the region of the cecum for five years. We have seen a substantial number of cases of actinomycosis and they always progressed to a degree that either the patient died of the disease in the course of a few months or there have been other foci of infection scattered throughout the

body which have made the diagnosis more obvious. I am going to rule out actinomycosis and that brings me back to what seems the most probable diagnosis in this case which is tuberculosis. I do not think tuberculosis fits the picture entirely but it accounts for the different elements of this case better than any other disease. I should expect ordinarily in tuberculosis that there would be an ulcer in the cecum and the discovery of blood in the stool examination. I am surprised that there was no more change for four years following the first operation. But I do know that tuberculosis will occasionally remain more or less dormant for a period as long as that and I think it is quite conceivable that it may have done so in this case. Therefore, I say it is tuberculosis.

DR. TRACY B. MALLOY: Perhaps Dr. Hampton can give you some help.

DR. AUBREY O. HAMPTON: This man was examined several times and we followed him with considerable interest. At the first barium enema these loops of dilated small bowel and this concave pressure defect on the cecum were found. The cecum is fairly smooth and there is very little spasm at this time. This may indicate that this is not tuberculosis, the cecum being so normal—except for evidence of extrinsic pressure. We could not fill the ileum by enema. Barium by mouth filled the ileum and remained there for forty eight hours and although he had pain, as I remember it he did not act as though he were actually obstructed. I think he tolerated the barium unusually well. At the seventy two hour examination no barium was retained. The stomach and duodenum were perfectly normal. The chest was normal, gall bladder normal, in fact everything was normal except the terminal ileum.

This is the film taken after the second operation and it just shows the location of the abscess that was drained. This film was taken after lipiodol injection of the abscess and there was no doubt about its being behind and lateral to the ascending colon.

At the time of his third admission we filled the terminal ileum for the first time. There is a grossly irregular constriction of the terminal ileum and a fairly smooth cecum.

At the time we made the first examination we would have agreed with Dr. Miller that this disease was tuberculosis, but that was five years ago and I think that now we might change our diagnosis in fact we did.

DR. MALLORY: Have you anything to add Dr. Miller?

DR. MILLER: As a matter of fact I did not know you were going to ask me to say anything further about the diagnosis and while Dr. Hampton was speaking I asked Dr. Smithwick what it was and now I know. But as I reviewed it I thought of regional ileitis and ruled it out because I rather felt that the mass must be in

the cecum I interpreted the thickening of the ileum as being due to the hypertrophy from constant working against obstruction

CLINICAL DISCUSSION

DR REGINALD H SMITHWICK If the operative findings of the second and third operations had been more fully described in the summary I am sure Dr Miller would have reached the correct diagnosis

This case was a very interesting one to us who saw the patient for a period of six years. When he first came to the hospital he presented the picture of chronic obstruction of the small intestine. At the first operation his small intestine was tremendously hypertrophied and thickened throughout. In the right lower quadrant was a mass which, as I remember it now, was the size of a small grapefruit—a little larger than that described in the record—and also it could be felt by rectum before operation. At operation about a foot of small intestine was very adherent and ran around medially to the mass. The bladder was drawn over it and it was impossible to tell what it was except that it appeared to be behind and beneath the terminal ileum. The cecum was slightly thickened but apparently only by continuity to the mass. I think if that had been brought out it would have been obvious that the disease was not primary in the cecum. However, we had no idea what it was at that time and the only thing to do was to short-circuit this area, which was done, and he made a satisfactory convalescence and remained well for several years.

DR MILLER What was the mass?

DR SMITHWICK It was a chronic inflammatory mass, the character or origin of which we could not interpret. It gradually and entirely disappeared so far as one could tell on abdominal and rectal examination. In the course of two or three months after his short circuiting operation he felt so well that he went back to work and he was loathe to have anything further done at that time. At the end of four years, however, he began to lose weight, was tired, had anemia, chills and fever, and became so run down that further operation became necessary.

At the second operation, some four years later, there was no very large mass. When this was exposed, as contrary to the summary here, an abscess was found beneath the terminal ileum. The abscess cavity contained about two ounces of thick pus and in this cavity lay a thickened appendix. In the wall of the appendix was an opening, in other words a fistula into the appendix, and apparently this pus was draining back into the intestine, probably through the appendix, although, as Dr Miller pointed out,

I do not believe and did not think at that time that the appendix was the origin of the abscess. In the presence of this abscess and thick pus it seemed inadvisable to resect the terminal ileum and colon at that time. Therefore, the abscess was drained and, as the record shows, it kept opening and discharging, and the record is correct in saying that after the abscess had discharged he felt much worse than before. He began to feel very miserable for a week or ten days every time we opened the fecal fistula and the abscess discharged.

At the third operation he had a large abscess which ran up behind the ascending colon, up to the third portion of the duodenum. At that time he was so miserable that something radical had to be done. The terminal ileum, cecum and ascending colon were removed. In separating the transverse colon and hepatic flexure from the duodenum a large opening was made in the second portion of the duodenum, because it presented as a part of the chronic inflammatory wall of the abscess cavity. Whether there was an actual fistula into the duodenum at this point before operation, I am not sure. Anyway, this hole in the duodenum was closed with great difficulty and at the time it did not seem a very satisfactory closure. His terminal ileum and right colon were removed and anastomosis was not done at that time. They were brought out of the upper end of the incision à la Mikulicz. He made an uneventful convalescence. Surprisingly enough the duodenum did not break open. He developed no duodenal fistula and later on the colostomy was closed.

At the third operation it was obvious that the process was regional ileitis. At the time of the first operation I had never heard of that disease. At the second operation we thought that diagnosis probable, and at the third operation it was perfectly obvious that that was what it was, and there were fistulae between the loops of small intestine and large intestine and this large abscess behind the descending colon, which represents practically all of the multiple complications and features of this disease which now is fairly frequently recognized but rarely seen in this form. Usually it is an acute abdominal emergency and usually the patients are operated on for acute appendicitis and an area of thickened terminal ileum, often with fibrin on its surface, is found. This represents the end result of treating these patients with multiple stage operation. I believe the present feeling is that immediate one-stage resection and anastomosis when the condition of the patient is satisfactory is perhaps the best way to do it because the longer you leave the lesion untreated the more complicated the process can become, so many fistulae form between the loops of adjacent duodenum and bowel.

PREOPERATIVE DIAGNOSES

First Operation Intestinal obstruction
Second Operation Subacute appendicitis
Third Operation Fecal fistula.

DR. RICHARD H. MILLER'S DIAGNOSIS

Tuberculosis of the cecum and surrounding tissues.

PATHOLOGIC DIAGNOSIS

Regional ileitis

PATHOLOGIC DISCUSSION

DR. MALLORY The resected specimen showed about what these cases usually do. The last portion of the ileum was markedly thickened, the wall very edematous. There were no perforations or open fistulae, the mucosa was deeply ulcerated and showed numerous tabs of hemorrhagic granulation tissue replacing the epithelium. The histologic picture of these

cases varies a good deal from case to case. A characteristic of many of the cases is the finding of collections of foreign body giant cells, sometimes simulate tuberculosis very closely, undoubtedly in the past some of these have been mistaken for tuberculosis. In particular case that was not a prominent feature and one would not even think of tuberculosis from the histologic picture.

Whether the appendix was involved by the same process I am not quite sure. On going over the sections again it seems to me the appendix is a little peculiar in type. The mucosa is hemorrhagic, whereas the rest of the appendix shows only a subacute infectious picture. I might say that in the inflammatory cells in the ileum and the appendix eosinophils are very numerous, so that probably correlates with the high blood eosinophilia.

The cecum as usual was entirely negative. Occasionally the process has been reported to involve the cecum but in most instances it is short at the ileocecal valve.

"A DOCTOR'S ODYSSEY"

Dr Le Roy Crummei, physician, teacher, and collector of old books, died in January 1934. Shortly after his death, on February 15, a brief review of his life and work was published in The New England Journal of Medicine, augmented by an appreciation of the man written by Mr J Christian Bay, librarian of the John Cierar Library in Chicago. To Bay's thoughtful essay are now added the estimations of others, in the form of a book*, supplemented with a brief life of Dr Crummei and a partial description of his books. Even more important than the tributes paid him by his friends are the numerous letters from and to Crummei which depict his world-wide travels, his flair for book-collecting and his love of life as a humanitarian.

In the course of twenty-five years Dr Crummei built up a superb collection of books on the history of medicine. Beginning with a few

*Beaman A Gaylord. A Doctor's Odyssey. A Sentimental Record of Le Roy Crummei. Physician. Author. Bibliophile. Artist in Living. 1872-1934. Baltimore. The Johns Hopkins Press. 1935. Price \$2.50.

standard reference works, he soon completed, except for one edition, all the printings of Sir Thomas Browne's *Religio Medici* and added the American medical classics of Drake, Rush, Morgan and others, ninety per cent of the great anatomies mentioned by Choulant in his *Geschichte der Anatomischen Abbildung*, every edition of the works of Gideon Harvey many of the publications of Paracelsus, Paré, Jenner, Sydenham, Bright, the Hunters and numerous other great physicians. We now know what has happened to most of this great collection, for it has enriched the libraries of the University of Nebraska Medical School at Omaha and the University of Michigan at Ann Arbor. Omaha received the Americana and most of the books printed after 1640, while the bulk of the collection, including about five thousand portraits of physicians, is now in Ann Arbor. Two catalogues of the collection were issued by his wife: one in mimeograph in 1925 and a second, printed in 1927. Each was limited to one hundred copies and they are now almost as hard to come by as some of Crummei's own books.

Thus gradually great private collections are added to permanent shelves, making the value of each rare book proportionately greater. With the Osler books in Montreal, the Streeter collection in New York, Jacobs' in Baltimore, Crummei's in Omaha and Ann Arbor, only a few outstanding medical libraries in this country are now in private hands. With two more great libraries almost on University shelves, it is indeed an expensive time for book-collectors but a glorious epoch for students of medical history. Canadian and American medical life has been made richer by Osler and Crummei, and men of their stamp, who have seen the need of such collections and, withal, have enjoyed the fun of book hunting and book bargaining. That men as far apart as Crummei and Osler could each find joy in building up great libraries speaks well for such an avocation for the physician.

THE MANHATTAN MEDICAL SOCIETY

The Manhattan Medical Society, founded in 1930 by Negro physicians of New York, has recently found it desirable to publish a pamphlet detailing its past, present and future activities. The main purpose of this brochure is to expound the conception of the Society of the Negro physician's place in the community, its thesis is an emphatic protest against any and all forms of segregation based on color.

Particularly abhorrent to the Society is the activity of the Julius Rosenwald Fund in establishing and aiding in the establishment of Negro institutions and hospitals. According to an open letter to Mr Edwin R Embree, presi-

dent of the Julius Rosenwald Fund "The Rosenwald hospitals are 'Jim-crow' in spirit and 'Jim-crow' in fact, and they establish in the minds of the white doctor and citizen a superiority complex and they also establish in the minds of the colored doctor and colored citizen an inferiority complex."

Other causes of discontent are variously dealt with the staffing of Veterans' hospitals and the activities of the Harlem Health Center.

The question of Afro-American relations has long remained a vexing discussion and no immediate solution is in sight. Temperate and thinking members of neither race would care to see the Negro's opportunities bounded by any limits other than his own abilities. The means of producing these opportunities is not so clearly seen. Unfortunately certain social prejudices exist and must be faced.

It would be well occasionally, to call back to mind the words of Booker T. Washington in his great Atlanta speech in 1895. In all things that are purely social we can be as separate as the fingers, yet one as the hand in all things essential to mutual progress.

"There is no defence or security for any of us except in the highest intelligence and development of all. If anywhere there are efforts tending to curtail the fullest growth of the Negro, let these efforts be turned into stimulating, encouraging and making him the most useful and intelligent citizen. Effort or means so invested will pay a thousand per cent interest. These efforts will be twice blessed—blessing him that gives and him that takes."

"There is no escape through law of man or God from the inevitable—"

The laws of changeless justice bind
Oppressor with oppressed
And close as sin and suffering, joined
We march to fate abreast."

The Massachusetts Medical Society

ANNUAL MEETING OF THE MEDICAL SECTION

THE primary object of the Annual Meeting of the Massachusetts Medical Society is to enable the members to foregather in good fellowship to renew old acquaintances and to make new friends among the physicians drawn to the meeting from all parts of the state. It is fitting that the meeting this year should be held in Springfield not only to permit the attendance of many men from the western part of the state who otherwise would find it difficult to be present but also to shake members from the eastern districts out of their medical ruts and allow them to enjoy the admirable medical and civic hospitality which will be offered.

The chief attractions on the program are the papers which are presented before the various sections. The quality and character of these papers determine to a large extent the success of the meeting. The program of the Section on Medicine has been so planned that it will appeal to all who attend. The general practitioners who will constitute the larger percentage of those in attendance, will find material that is of practical value presented by experts who speak their language. The specialist and more scientifically minded clinician will find information that is both timely and authoritative. The program has not been arranged with the purpose of presenting speculative medical hypotheses with intricate experimental procedures and results. To broaden the scope of the discussion no attempt has been made to arrange a symposium on one subject, but topics have deliberately been chosen from several fields.

Pathological states dependent on or conditioned by industrial hazards are assuming an increasing importance in medicine today. Dr. Alice Hamilton, the well known authority in this field, will speak on some phase of the subject.

Angina pectoris is a condition which is exacting its toll throughout this State as elsewhere. Any presentation of the successful management of this condition will be appreciated. It will be particularly pertinent therefore, to have the views of Dr. John Sproull of Haverhill who combines the standpoint of the general practitioner and the expert in the subject.

There is no clinician who has not been confronted with the problem of whether a transfusion may not be indicated and all such will be helped by the authoritative discussion of Dr. Arlie V. Boek of Cambridge on the uses and abuses of this procedure.

There is hardly a field in medicine in which more experimental and clinical work has been done in recent years than in liver disease. New theories of etiology, new classifications, new tests of hepatic function are all so numerous that it is difficult to winnow the wheat from the chaff. Dr. Chester M. Jones of Boston will summarize some of the newer knowledge in this field.

In spite or perhaps because of the fact that salt is such an integral part of our normal diet physicians have paid very little attention to the proper administration of sodium chloride in disease states and the rules they follow are more likely to be founded on tradition than on modern scientific knowledge. Much can be done to enhance the comfort of patients, to control symptoms and even to anchorate the course of disease by a proper appreciation of the use of this ubiquitous and very necessary substance. Dr. Allen S. Johnson of Springfield will present a paper on sodium chloride therapy.

DIET AND PREGNANCY

The ideal diet during pregnancy is one which provides all the essentials, eliminates the un-

*A series of short selected articles by members of the Section is being published weekly
Comments and questions by subscribers are solicited and will be discussed by members of the Section

essentials, and keeps the patient from gaining too much weight Diet is no problem in the normal pregnancy during the first three months The average patient keeps herself well by eating frequently every one and one-half hours or every two hours rather than three times a day, and usually eating anything that she wants to eat The only aim at this time is that food shall be eaten The question of weight at this time does not arise because it is the unusual patient who gains much of any during the first three months The average patient, eating more than she normally would eat, doing much less than she normally would do, because of the demands of pregnancy for rest, and losing no meals, often loses, and very, very rarely gains much of any weight

After the need of frequent meals to control the normal nausea and vomiting of pregnancy has passed, the question of what to eat and how much to eat arises An ideal diet is a mixed diet containing protein, carbohydrate, fat, calcium and vitamins in sufficient quantity to provide for the growing fetus and at the same time keep the mother's weight from increasing unnecessarily As the average patient gains none during the first three months in pregnancy so does the average patient gain very little the last ten days or two weeks of pregnancy, unless she develops edema, so it is between three and one-half and eight and one-half months that the question of excessive weight is to be fought against One-half pound a week gain during these months allows the patient to maintain almost her normal weight What she puts on is mostly pregnancy

The average caloric need for twenty-four hours, without putting on excessive weight, is met by the ingestion of, first, a quart of skimmed milk This may be taken raw or used in soups It contains protein, carbohydrate, very little fat and plenty of calcium Orange juice, because it contains calcium and carbohydrate, should be used in generous quantities Tomato juice, rich in vitamins, should be taken once or twice a day Beyond the carbohydrate found in milk, orange juice and tomato juice, the five and ten per cent vegetables, taken in liberal quantities, provide all the additional carbohydrate that is necessary, without putting on unnecessary weight

Protein is a constituent of milk, beef, chicken, lamb, fish and eggs The pregnant patient needs a lot of protein, and protein is protein whether it is taken in the form of milk or in the form of meat It is an old-fashioned idea that meat should be restricted, and the average pregnant patient should consume daily at least three-quarters of a pound of beef or its equivalent Liver, sweetbreads and kidneys, because of their blood-stimulating properties, are foods

which pregnant patients should eat frequently. One of the three of these twice a week is almost an essential. Fat free cottage cheese is one method of supplying plenty of protein.

Fat is necessary in only small amounts and is best obtained by eating a pat of butter with each meal. Fried foods, pork and fat on meat are contraindicated.

On a diet mixed with the above-mentioned foods, the average patient is perfectly happy, gains satisfactorily, keeps down her increase in weight to the minimum, saves energy by not wasting energy in storing up too much fat, saves fatigue by not carrying around the unnecessary burden which an abnormal gain in weight necessitates.

Between meals a glass of skimmed milk and a few rye crispas appease hunger, relieve indigestion and do not add weight. Of course there are pregnant patients who gain very little no matter what they eat. If they will eat the essentials and not gain much weight, it does not make any difference what other foods they eat, but the patient who adds too much weight usually gains because she eats too many carbohydrates, and if the increase in weight is extravagant, all bread, potato, thick soups with a flour base, marmalade, canned fruits, preserves, candy, and excessive fat should carefully be eliminated.

At present there is no way by diet of specifically limiting fetal weights. It is a fair assumption that if the mother is not gaining inordinately, her baby is not gaining too much, but this is only an assumption.

The need of iron during pregnancy has been well established and all pregnant patients, although they are on a good mixed diet, which should provide all the iron that they need, should take some form of ferrous sulphate the equivalent of 12 grains a day. This keeps the blood picture at a normal level and does away with the secondary anemias that may otherwise result.

From the standpoint of calcium metabolism, in this climate, when the amount of sunlight is not to be depended upon, patients should routinely take some form of halibut oil.

Condiments may be taken as desired with the exception that salt should never be eaten lavishly.

FELLOWS, TAKE NOTICE!

An analysis of the unpaid annual dues of Fellows of the Massachusetts Medical Society is underway. By vote of the Council, the names of those Fellows whose dues have not been paid by March 2 will be taken from the mailing list of *The New England Journal of Medicine*.

Fellows are urged therefore, to pay promptly their annual dues to their District Treasurers so

that their names will not be removed from the mailing list.

Delay in making payment leads to disappointment on the part of Fellows who will not, therefore, receive the *Journal*.

Treasurers, also, of the several District Medical Societies should forward to the Treasurer of the Massachusetts Medical Society a record of all payments of annual dues.

BOSTON MEDICAL LIBRARY

DR. RICHARD BRIGHT, 1789-1858

It is so frequently the case that a man's name becomes associated with some one disease or even a particular symptom, that the generality of physicians may be unaware that the particular discovery was only one of many made by the individual in question. It further more, not infrequently happens that the observation which becomes attached to the name is of less importance than some other discovery he may have made. What is pretty certainly true is that whatever it may have been which has been singled out and associated with the observer's name, was found out as the result not of chance alone, but in consequence of persistent and painstaking study on the part of the individual so distinguished. It is, therefore, important that this fact should not be too heedlessly passed over if we are to arrive at the true significance of the lives of those who have made a reputation for themselves in the medical world. It cannot be too strongly emphasized that no real advances can be made in the progress of medicine without someone putting in hard and time-consuming drudgery and it is to those who are not discouraged by repeated failures that reward for their effort ultimately comes.

This was notably the case with Richard Bright. Born in Bristol, England, in 1789, he began a medical education so far as its preliminary stages were concerned at Edinburgh and continued it later in London. In 1808, he matriculated in the arts course at Edinburgh under Dugald Stewart, Playfair and Leslie and a year later joined the medical school under Monroe, Hope and Duncan. Fondness for travel led him to interrupt the courses at Edinburgh for a year which was passed in Iceland studying botany and zoölogy. Returning to London, medical studies were resumed under Crichton and Babington and, through the latter's interest was aroused in geology. It was during this period that he is supposed to have been stimulated by Sir Astley Cooper to study pathology. Besides Cooper's influence, Travers and Clunes were important factors in shaping his career. In 1812, after returning to Edinburgh, medical studies were undertaken with the then celebrated

Dr. Gregory. Interest in the study of geology and natural history was continued under Professor Jameson.

After graduation here in 1813, two terms were spent at Cambridge but, not being able to follow up his interests there, he again went to London to work in the Dispensary with Dr. Bateman. The urge for travel induced him to spend the winter of 1814-15 in Berlin and Vienna, studying particularly with Hildenbrandt. On the way home, he visited Hungary and stopped at Brussels, which place was reached shortly after the battle of Waterloo. Here time was devoted to study among the many sick and wounded in the hospitals of that city. Upon a third return to London, he became attached to the London Fever Hospital and the Public Dispensary. At the Fever Hospital, fever was contracted which threatened to end his career. This experience was made an occasion for again undertaking a continental travel tour, visiting France, Italy and Germany.

In 1820 he finally settled in London, was elected to become an assistant physician at Guy's Hospital where the most arduous years of his life were destined to be spent. During a continued service in this institution until 1843, advancement at first from the position of assistant, to full physician and after 1840 to consultant, followed. He was instrumental in building up the reputation of the medical school of Guy's Hospital, largely through indefatigable energy. Besides giving prepared lectures, he spent for several years, six hours a day in the wards and postmortem rooms of that institution. As an expositor of knowledge, he was not in the same class as some of his colleagues with whom, however, he worked in harmony.

It was from the wards of Guy's and its postmortem room that the data were accumulated that enabled him, in 1827, to identify the presence of albuminuria with pathological conditions in the kidneys. The presence of a coagulable albumin in the urine had been recognized for generations but its association with kidney lesions had never been demonstrated. As a result of repeated observations, he was able to announce that he had never seen a coagulable albumin in the urine of a patient, whose kidneys were subjected to examination, that did not have a demonstrable lesion of the kidney substance and it must be remembered that this conclusion was reached almost wholly from a study of gross pathology. Besides this work on the kidney, he made numerous other important observations. He was not a theorizer but a very keen observer and had the happy faculty of synthesizing his observations.

Bright was one of the first to describe acute yellow atrophy of the liver and the first to call attention to the frequent association of a heart murmur with chorea. Lack of ability to teach

made him less well known among his English colleagues than his more brilliant associate at Guy's, Dr. Addison, but he was far better known abroad. He wrote quite extensively for current periodical literature and was the author of two or three books, the most important being a two volume collection of "Reports on Medical Cases", said to be the most important contribution to the subject of morbid anatomy ever made by any one person in England. From the time in 1836 that Guy's Hospital Reports were first published, Bright was a frequent contributor. In 1816, he was admitted as a licentiate of the College of Physicians and became a Fellow in 1832. He gave the Gulstonian lecture in 1833, and in 1837 was the Lumlan lecturer upon "Disorders of the Brain."

When Queen Victoria came to the throne in 1837, Bright was appointed physician extraordinary. The Royal Society honored him with membership in 1821 and at about the same time he was awarded a medal by the Institute of France. He did not make such a brilliant and rapid rise to prominence in practice in London as many another but eventually was probably consulted upon more important cases than any of his contemporaries. He had an attractive personality, was a linguist of note, cultivated in art and had considerable technical ability as an artist, was well informed in two or three sciences and had profited much through travel and his social connections. Withal, he was simple, gracious and tactful in all contacts with his fellow man. At his death, which occurred on the sixteenth of December, 1858, he was survived by his second wife, three sons and two daughters. One son was at one time Master of University College at Oxford and another was a physician practicing in Cannes. Though he was not to be classed as a brilliant man, his work upon the diseases of the kidney has ranked him along with Laennec, as one of the two physicians who contributed the most valuable discoveries in the first half of the nineteenth century. Certainly he has earned a place among the first fifteen or twenty on the roster of outstanding English physicians.

MISCELLANY

RADIO BROADCAST

February 8, 1936

Yankee Network

Introduction by Radio Announcer
Ladies and Gentlemen

For the next thirty minutes the facilities of this Station have been placed at the disposal of the Massachusetts Medical Society. This organization is represented here tonight by its President, Dr.

Charles E. Mongan, of Somerville by its Secretary Dr. Alexander Begg of Boston, and by the Chairman of its subcommittee on Social Legislation and Insurance, Dr. Michael A. Tighe of Lowell.

Dr. Begg is the Dean of the School of Medicine of Boston University. Dr. Mongan and Dr. Tighe are practicing physicians of many years standing and both are Fellows of the American College of Surgeons. All three are members of the American Medical Association and are generally recognized by their professional brethren as well qualified to present the views of the Massachusetts Medical Society in the matter of Compulsory Sickness Insurance—the subject of this broadcast.

You will first hear from Dr. Mongan who will speak to you briefly about the history aims and purposes of the Massachusetts Medical Society. He will then develop the subject matter of the broadcast by means of certain questions to which Dr. Begg and Tighe will respond.

May I present Dr. Charles E. Mongan, President of the Massachusetts Medical Society.

Dr. Mongan

The Massachusetts Medical Society numbering 5106 members was founded in 1731. It is the oldest Medical Society in the United States with a record of uninterrupted meetings from its incorporation to the present time. Its life is nearly coincident with that of the Republic. At the time of its incorporation there were only two Medical Schools in the Country one at New York and one at Philadelphia and many of the thirty-one incorporators of the Society obtained their medical training in foreign countries.

The Massachusetts Medical Society has since its earliest days stood for the highest ideals in medical standards. It has insisted that the practitioners of medicine should have some premedical education. When our Society was first organized strange as it may seem to us of the present day there were some practitioners of medicine who were almost illiterate. The Medical Society's aim was to improve medical education, to guide the progress of medical practice to eliminate charlatans and quacks by insisting upon sane and scientific methods in the practice of medicine and to create as soon as possible a medical school where the future practitioners of medicine might be trained.

The Society took interest, very early in matters of Public Health. In 1842 it successfully petitioned the Legislature to pass a law compelling the reporting of births, marriages, and deaths. It was one of the earliest societies to take an active interest in the reduction of deaths from pulmonary tuberculosis and through its efforts a system of state hospitals for the care of the tuberculous was instituted in Massachusetts. Through the efforts of one of its former Presidents Massachusetts was the first of all the States to adopt humane methods in the care of the insane. Sanitation and pure water supply for human consumption have been advocated by the Massachusetts Medical Society.

The Massachusetts Medical Society was instru-

mental in the establishment of the Massachusetts State Board of Health in 1869. This was the first Board of Health in the United States of America.

Time will not permit me to elaborate upon all the Acts which the Massachusetts Medical Society has sponsored for the health of the people but allow me to say that the same care and vigilance for public welfare is alive in the Society today. The Economic Security Act which recently passed the House of Congress is one of the most important pieces of legislation of recent times for most of the text of this Act concerns the health of the people and promises economic security to the aged.

The proper administration of this Act calls for the coöperation of the medical profession especially in the fields of maternity welfare, child welfare, crippled children and sickness. Tonight we will discuss with you that portion of the program which has not been announced but is being considered. We will try to give you a fair statement concerning Compulsory Sickness Insurance.

First Compulsory Sickness Insurance means that a certain low income group of the citizens of Massachusetts must be insured against the hazards of sickness. This low income group is sometimes defined as those who earn \$3,000 a year or less or the aggregate earnings of the family are \$3,000 or less. Domestic help, farm help, casual workers and certain municipal State and Federal employees are exempt from the provisions of the proposed law.

In the set up of such insurance the employer contributes a certain amount, the employee an equal amount and the Government an amount which when added to that obtained from the other two sources will perpetuate the system.

It would seem then that the general idea of Compulsory Sickness Insurance is to provide first class medical care for those economically unable to provide it for themselves and to do it by spreading the costs over such great numbers as to make the costs to the individual relatively small.

QUESTION PERIOD

Dr. Mongan: Are my statements correct, Dr. Tighe?

Dr. Tighe: I think that they are, Dr. Mongan.

Dr. Mongan: Well, Dr. Tighe, this sounds like a pretty good thing.

Dr. Tighe: Yes, Dr. Mongan, the wisdom of this as a statement of an ideal cannot be questioned and it would be most difficult to find any doctor who was not in entire sympathy with such a proposal. However, thinking men are wont to distinguish between a stated ideal and the application of that ideal in everyday life. As a distinguished Massachusetts editor recently put it: "Man does not perform his functions in a vacuum."

In the field of human relations there are frictions which are just as constant as those encountered in mechanics but with this difference that whereas mechanical frictions can be reduced to a constant mathematical minimum, those developed as the result of human relationship in complex society cannot.

Fifty years' experience with Compulsory Sickness Insurance in Germany and twenty-five years' experience in England have clearly demonstrated that this ideal, which is so very attractive in the abstract, has not been, and cannot be realized in practice

Dr Mongan Dr Tighe, will you tell something more about these human relation frictions?

Dr Tighe In the first place, Dr Mongan, there has never been a demand on the part of the people for Compulsory Sickness Insurance Secondly, political expediency represents its parentage Fifty years ago, Bismarck used it in an attempt to destroy the growing influence of the Social Democrats Twenty-five years ago, Lloyd George picked it up and waved it in all the glory of its idealism before the English workman, when he found himself in such a tight political position that he needed the workman's vote to maintain his control of the English Government Thirdly, everyone knows that whenever politics touch the ideal, the ideal is usually sacrificed on the altar of expediency Again, Labor has always been more interested in a steady job at a decent wage than in the soup kitchen Again, the man of labor, given the opportunity to support himself and family decently, will do a pretty good job in the care of the intimacies of his home He wants the doctor of his own choice to care for him and those he loves He wishes that doctor to be responsible to him and not to a political bureaucrat In other words, he is strongly in favor of the law which makes his home, his castle!

Labor knows that it pays not part, but the whole, of the Compulsory Sickness Insurance Bill inclusive of its tremendous administration costs Labor knows that the employer's share is not a gift, but something either taken out of wages or tacked on to the cost of the article produced, which in turn labor must buy He knows that he must likewise pay the government's share either directly or indirectly through taxation He knows how top-heavy and shot through with bureaucracy the administration of such systems becomes He knows that in Germany, for every doctor giving medical service, the politicians have matched that doctor with an administrator It takes as many administrators in Germany to administer the act as it does doctors to care for the sick He knows that there are 3,000 sections to the German Laws on Compulsory Sickness Insurance, and he fully appreciates the difficulties which confront the average workman in seeking his rights in the presence of such complicated legal machinery He knows that during the last year, for every dollar spent on the insured English workman, fifteen cents was spent on administration And finally, he thinks \$23,800,000 is a pretty large sum to spend on the administration of this system, which, at the best, provides him with second-class medical care

Dr Mongan I think you make it rather clear, Dr Tighe, why American Labor has been so cool toward this type of legislation Will you kindly proceed?

Dr Tighe It is human nature to want to get something in return for one's expenditure In this way, those pretending to be sick are encouraged The temptation to dishonest practices, on the part of the patient and doctor alike, is everywhere recognized as one of the great evils of Compulsory Sickness Insurance

Dr Mongan The English system, Dr Tighe is being talked of as the model for the proposed American plan May I ask you some questions about this English system?

Dr Tighe Yes, indeed, Dr Mongan

Dr Mongan Is the English workman's health better since he had insurance?

Dr Tighe It is not, and if we are to accept the figures of the British Minister of Health, for a six year period, 1921 to 1927, we must arrive at one of two conclusions, either his health is very much worse or he has developed malingering to a fine art These figures tell us that the incidence of sickness as indicated by benefit claims had jumped during the period 41 per cent for men, 60 per cent for unmarried women, and 106 per cent for married women

Dr Mongan Have you any information, Dr Tighe, as to how mortality rates have been affected?

Dr Tighe Well, I know this, Dr Mongan, that from 1913 to 1933, the mortality rates in England dropped less than 10 per cent, while in this country, during the same period, these rates dropped 21 per cent

Dr Mongan Dr Tighe, have you any figures by which the number of days which the English workman loses from industry due to illness, may be compared with those lost by the American workman for the same reason?

Dr Tighe Yes, I have, Dr Mongan The English workman loses ten days each year because of sickness, and the American workman six and one-half

Dr Mongan What about preventive medicine in England under Compulsory Sickness Insurance?

Dr Tighe Well, Dr Mongan, in England, the interest has been focused on those actually ill, and the emphasis has been largely away from preventive medicine as we know it in this country

Dr Mongan Dr Tighe, are you able to tell us something about the amounts expended for poor relief in England under the insurance? You know it was expected that these amounts would be lessened

Dr Tighe These amounts have not been lessened, but quite the contrary They have continuously increased, and within the last two years, the most extensive measures ever proposed in England, have been put into operation

Dr Mongan Dr Tighe, if Compulsory Sickness Insurance has failed to realize its ideal in a country like England, with its homogenous make-up, would you expect even greater difficulties with such a system in the United States?

Dr Tighe Yes, indeed, Dr Mongan The make-

up of our country is extremely heterogeneous. The traditions of the origin of our people are extremely variable. These traditions in so small measure still are the dominant influences in the home, and in the problems, such as sickness, which closely touch the home. Furthermore Dr Mongan we are forty-eight small nations each with its own difficulties and its own problems and it would seem to me that it would be impossible for our Federal Government to formulate a Compulsory Sickness Insurance system that would meet the problems of all since we well know that the problems of no two are alike.

Dr Mongan Dr Tighe have you any information as to how insurance actuaries feel about Compulsory Sickness Insurance as an insurance scheme?

Dr Tighe My information and contacts make me feel that they do not think much of it as an insurance because of the absence of certain factors which are elemental to good, sound insurance. First our insurance laws are very insistent that all reserves be built up by any insurance scheme which is offered to the people. Compulsory Sickness Insurance makes no provision for such reserves. Secondly insurance men know that birth, old age and death permit of fairly accurate determinations. They feel, however, that there are so many moral elements which enter into the business of Compulsory Sickness Insurance as to preclude the possibility of sound actuarial guidance.

Dr Mongan Dr Begg you are the Dean of the Medical Department of Boston University and as such have many contacts with young men and much to do with their training in medicine. What effect would Compulsory Sickness Insurance have on the type and quality of the man presenting himself to you for training in medicine?

Dr Begg Today only the finest intellects are able to meet the entrance requirements of Medical Schools. Under Compulsory Sickness Insurance I am sure we would have to let the bars down considerably. This, of course, would lower the whole standard of American Medicine.

Dr Mongan Dr Begg how high is the American standard of Medicine today?

Dr Begg The highest in the world.

Dr Mongan Do you think, Dr Begg that the prevalence of Compulsory Sickness Insurance in Europe explains in any way the tendency to lose its medical leadership to the United States?

Dr Begg Yes, I do, because it is very difficult in any endeavor to maintain leadership when individual initiative is destroyed.

Dr Mongan Dr Begg could you tell us whence in your opinion, comes a great deal of the urge for Compulsory Sickness Insurance in this country?

Dr Begg Well, Dr Mongan I think it came from the majority report of the Committee on the Costs of Medical Care and later received a certain acceleration from the depression. This is the committee that was financed by the social foundations and which spent close to a million and one-

half dollars in its investigations. This committee found that there were ample facilities for medical care but that these facilities were not available to all the people.

Dr Mongan Can this majority report of the Committee on the Costs of Medical Care in this conclusion which you have just mentioned, have been speaking of Massachusetts?

Dr Begg No Dr Mongan this committee in its investigations did not touch Massachusetts at all and consequently cannot speak for Massachusetts.

Dr Mongan Dr Begg may I ask you as the Secretary of the Massachusetts Medical Society a question.

Dr Begg Yes indeed Dr Mongan.

Dr Mongan Is there a feeling in the Massachusetts Medical Society that there may be needed some change in the way in which medical care is made available to the residents of Massachusetts?

Dr Begg Yes and in response to that feeling the Massachusetts Medical Society has plans for a survey of medical conditions in certain key cities in Massachusetts. It is expected that this survey will demonstrate whatever difficulties there are. It is felt that when these studies are complete the Society will be in an excellent position to sponsor whatever remedies are needed and this the Massachusetts Medical Society is pledged to do.

Dr Mongan We hear Dr Begg much talk about the present high cost of sickness. Have you any ideas as to how these costs might be very materially reduced?

Dr Begg I believe I have. In the first place I think it is very pertinent, Dr Mongan to contrast these costs of illness, as they affect the physician, with the other common costs in American life. The average American family pays one hundred and fifty dollars for automobiles, sixty-seven dollars for tobacco, thirty-seven dollars for candy, thirty-four dollars for soft drinks and chewing gum, twenty-five dollars for radios and twenty-four dollars annually to the doctor for its sickness care. The whole sickness bill of course is much larger but it is larger because the American public has many mistaken ideas as to what constitutes good medical care. Let the public cease its demands that hospitals maintain elaborate hotel-like accommodations, which add nothing to the successful diagnosis and treatment of disease. Let the public cease its demands for special nursing care in its trivial complaints. Let the public divert to its legitimate sickness costs the \$475,000,000 which it annually spends on quacks, charlatans, and nostrums and it will have gone a long way toward reducing its sickness bill to a minimum.

Dr Mongan The proposed legislation of Compulsory Sickness Insurance brings into our social life a new and unusual element, an element which forecasts a lowering of professional standards and professional practice. If Compulsory Sickness Insurance is ever adopted in any State in the Union, it will mean lay or political domination of the Med-

ical Profession The administrators of this law will be appointed by the Governor

In Massachusetts it would mean turning over the care of more than 1,500,000 people to a politically appointed commission The most intimate relationship of the sick person with his physician will no longer be a private matter but will inevitably become a public matter Generally speaking, the American people do not take kindly to compulsion But the idea of compulsion in Compulsory Sickness Insurance does not include all the people, but only a certain portion of the community who are labeled "A Low Income Group"

All compulsory legislation in Massachusetts, so far as I have been able to learn, is comprehensive and includes all the people Compelling a certain portion of the community to obey a certain law is quite new and dangerous

If we look about we can observe how Governmental supervision works in comparison with private enterprise Government control is not so effective

Has the Massachusetts Medical Society anything to offer in the way of adequate care for the sick? In the first place no one has questioned until now, the adequacy of medical care in Massachusetts No survey has ever been made, notwithstanding the fact that the invested capital in philanthropic institutions established for the purpose of caring for the sick is \$136,000,000 This statement does not include State Hospitals or certain City Hospitals in Massachusetts In 1933 these philanthropic institutions took care of 700,000 people, 300,000 of whom did not pay for their medical care Massachusetts is not like any other state in the United States It is feared by some students of social legislation that philanthropic hospitals could not be maintained at their present high efficiency if sickness insurance should prevail, and that inevitably these large institutions would fall under the control of the State

In Massachusetts the per capita wealth is greater than that of any other state with the possible exception of Connecticut The per capita share of money deposited in the savings institutions of all kinds (this includes savings banks, cooperative banks, savings departments of trust companies, and national banks) is greater than that of any other state in the Union Massachusetts is fast becoming a state of many and varied industries and our problems are very different from those of other states I also think that it will be admitted by most people that the private practice of medicine is more satisfactory for all citizens, than the governmental practice of medicine would be for a part of the community The position of the Massachusetts Medical Society can be stated as follows It opposes governmental or lay domination of the care of the sick It is at the present time making a survey of the adequacy of medical care available to Massachusetts citizens If it is found that medical service can be more adequately given, the Society pledges itself to do so, and the services will be those that will be best fitted to the social, financial, and economic condition of the citizens

Dr Mongan closed with thanks to WNAC for its graciousness in permitting the use of its broadcasting facilities

RECOGNITION OF DR HENRY A CHRISTIAN'S BIRTHDAY

At the regular Clinical Pathological conference held at the Peter Bent Brigham Hospital at noon on February 17, there was presented to Henry A. Christian, a volume of medical papers dedicated to him by his former students, colleagues and house officers, as a token of affection on his sixtieth birthday

There was a large attendance and the presentation was made by Professor Francis G Blake of New Haven Dr Blake in his address treated the volume as a pathological specimen, exhibiting all the various phases of disease usually seen on a medical service

Dr Christian in his reply emphasized his own happiness in his pupils and associates and amusingly noted that "in keeping with Brigham tradition the volume was issued *on time*"

The volume contains 1,000 pages of papers covering almost all phases of internal medicine and about equally divided between general articles, case reports and clinical and experimental research The contributions are geographically distributed as well About one half the articles represent original research which will probably not appear elsewhere

The edition is a limited one and the few copies available may be obtained from Dr Robert T Monroe at the Peter Bent Brigham Hospital

FIRE DESTROYS THE EXECUTIVE BUILDING OF MIDDLESEX COLLEGE, WALTHAM

The daily papers report that the executive building of Middlesex College was destroyed by fire the night of February 18

THE ELECTION OF DR EDWARD A KNOWLTON

At the annual meeting of the Federation of State Medical Boards, held at the Palmer House in Chicago on February 17, 1936, Dr Edward A Knowlton, of Holyoke, Massachusetts, and member of the Massachusetts Board of Registration in Medicine, was elected Vice President of the Federation for the ensuing year

THE MEDICAL HISTORY OF THE BLIZZARD OF 1888

Dr S M Strong of 42-33 Kissena Blvd of Flushing, New York, is interested in compiling data relating to the experiences of medical men in connection with the blizzard of 1888

He, with a number of friends, has organized a "business-like historic society" which has been known as "The Blizzard Men of 1888" The object of this organization is to collect individual accounts of experiences in connection with this storm which,

when compiled will give a history of this catatrophe.

It is hoped that physicians will contribute an account of unusual experiences at that time. Such recitals may be sent to Dr Strong

CORRESPONDENCE

A CRITICISM OF SENATE BILL 323

February 10 1936

Dr Louisa Paine Tingley*
9 Massachusetts Avenue
Boston Massachusetts

Dear Dr Tingley

I wish to call to your attention Senate Bill 323 concerning opticians and optometrists which might be of interest to you personally. There will be a hearing on the bill before the Commission on Public Health and Safety before it is submitted to the House or the Senate.

The objectionable feature of this bill is that despite the fact that physicians are exempt from examination they are, however subject to such rules and regulations as the Board of Optometry may dictate. This board, composed of four optometrists and one optician will thereby rule and regulate oculists in your state.

An article in a recent issue of *The Columbia Optometrist* advocated that every refractonist and every oculist be obliged to pass the optometry examination and an effort was being made to introduce such legislation in every state.

I feel sure you will agree that continued encroachments in our field as in other divisions of medicine have resulted in granting powers to different outlets—a result not to the best interest of medical science or to that of the public.

This letter is submitted for your information and I trust you will endeavor to defeat this phase of Bill 323 as it will assist us here in Connecticut if unsuccessful in your state. May I ask you to acquaint your fellow oculists with the situation?

Sincerely yours

(Signed) WM F REARDON President

Eye Ear Nose and Throat Society
of Hartford.

750 Main Street,
Hartford Connecticut.

Submitted by Dr Tingley

NOTICES

BOSTON DISPENSARY

25 Bennet Street Boston
Medical Conference Program
9-10 A M., March, 1936

Tuesday March 3—Bursitis Dr John D Adams
Wednesday March 4—Multiple Myeloma Dr
H. E. MacMillan.

Thursday March 5—Nephritic Clinic. Dr R. W. Buck.

Friday March 6—The Importance of Exact Diagnosis in Joint Disease. Dr Walter Bauer

Saturday March 7—The Neuroses Case Presentation. Dr Joseph H Pratt.

Tuesday March 10—Mistakes Made in the Diagnosis and Treatment of Syphilis. (Continued) Dr F M Thurmon

Wednesday March 11—Indications for Radiation Therapy. Dr C E Dumas

Thursday March 12—Gastrointestinal Clinic. Dr K S Andrews

Friday March 13—Lung Abscess. Dr Frederick T Lord.

Saturday March 14—Hospital Case Presentation. Dr S J Thannhauser

Tuesday March 17—Analysis of Case of Poliomyelitis Seen on the District Service during the 1935 Epidemic. Dr Edith Robinson

Wednesday March 18—Quantitative Studies in Nasal Obstruction. Dr H. J Sternstein

Thursday March 19—Social Service Case Presentation. Miss Edith R. Canterbury

Friday March 20—Studies in the Interrelation of the Thyroid and Adrenal Glands. Dr Elliott C. Cutler

Saturday March 21—Hospital Case Presentation. Dr S J Thannhauser

Tuesday March 24—X-Ray Demonstration. Dr Alice Ettlinger

Wednesday March 25—Electrosurgery of the Abdomen. Dr Lester Whitaker

Thursday March 26—Blood Clinic. Dr I. Olef

Friday March 27—Thyroid and Psyche. Dr James H. Means

Saturday March 28—Hospital Case Presentation. Dr S J Thannhauser

Tuesday March 31—Pediatric Case Presentation. Dr Francis McDonald.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday March 5 in the Amphitheatre of the Peter Bent Brigham Hospital Dr C Sidney Burwell, Dean of the Harvard Medical School, and Physician Peter Bent Brigham Hospital, will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12 staff rounds will be conducted.

THE INTERNATIONAL CONGRESS OF PHYSICAL MEDICINE

The International Congress of Physical Medicine will hold its next regular session in London England May 1-16 1936.

This Congress has a large membership representing forty different countries. The coming session will be held under the patronage of the British Gov-

enment The program, which will be based on advances in physical therapy technique particularly the scientific research developments, includes the following subjects for discussion

1 The physical and biological study of physical agents especially those which are of recent discovery and invention

2 The clinical and therapeutic indications of the different methods of physical treatment

3 An inquiry into the teaching of physical medicine in this country

The Congress will be in session for five days and a definite program of papers of general interest, which will be published in the near future, will be organized for discussion

The Congress has been subdivided into six sections

- a Kinesitherapy
- b Physical Education
- c Hydrotherapy and Climatotherapy
- d Electrotherapy
- e Actinotherapy
- f Radiotherapy and Radium Therapy

At the morning sessions, addresses will be given on a subject of general interest to all members of the Congress

There will be an exhibition of electro-medical apparatus

Special discussions on physical culture for recreation, remedial exercises in the treatment of the sick and on physical training have been organized

Other discussions will include (1) short wave high frequency electrical currents, (2) the production of pyrexia by physical methods and (3) sun bathing for the healthy and in the treatment of disease

Physicians interested in visiting this Congress are requested to communicate with Dr William D McFee of Boston, who has been delegated to organize the American contingent

WILLIAM D McFEE, M.D., *Vice President,*
International Congress
of Physical Medicine

41 Bay State Road,
Boston, Massachusetts

UNITED STATES CIVIL SERVICE EXAMINATIONS

Associate Public Health Engineer, \$3,200 a Year
Assistant Public Health Engineer, \$2,600 a Year
United States Public Health Service,
Treasury Department

Applications must be on file with the United States Civil Service Commission at Washington, D C, not later than March 16, 1936

The United States Civil Service Commission announces open competitive examinations for the positions named above Vacancies in these positions in the field and in positions requiring similar qualifications will be filled from these examinations, un-

less it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion The salaries named above are subject to a deduction of 3½ per cent toward a retirement annuity

Duties—To supervise or perform research in public health engineering, to give advisory assistance to, and to aid in the organization of, State and local health departments, and to conduct general public health engineering activities In the performance of these duties the maintenance of diplomatic supervisory and administrative relationships with health officials and with cooperative agencies is required

REPORTS AND NOTICES OF MEETINGS

GREATER BOSTON MEDICAL SOCIETY

The Greater Boston Medical Society met February 4, 1936, at the Beth Israel Hospital Dr Harry Linenthal, president of the society, presided, and introduced Dr Richard Lewisohn of the Mount Sinai Hospital, New York City, who spoke on the topic Recent Advances in the Surgical Treatment of Chronic Duodenal Ulcer The subject of the proper surgical treatment of chronic duodenal ulcer has been extremely controversial since the introduction of gastroenterostomy some fifty years ago In 1920 the operation of partial gastrectomy in the treatment of duodenal ulcer was introduced, and there has been increasing use of this method since that time

Some surgeons have maintained that every case of peptic ulcer should be treated with gastric resection This view is not generally endorsed, since the mortality from resections of very high gastric ulcers is nearly twenty per cent, a rate too high to justify the procedure The vast majority of ulcers, however, are in the distal portion of the stomach, or in the duodenum and can be removed without undue danger In the hands of an experienced surgeon the mortality from partial resection of the stomach in these latter cases is no higher than that from gastroenterostomy

Gastroenterostomy as a treatment for nonobstructing duodenal ulcer is unsatisfactory for two reasons First, it frequently fails to relieve ulcer symptoms, since the gastric contents are not sufficiently lowered in acidity and continue to pass by way of the pylorus instead of by the gastroenterostomy stoma, thus continuing the irritation of the ulcer bed Secondly, 34 to 50 per cent of ulcer patients with gastroenterostomy subsequently develop gastrojejunal ulcers, a very serious complication Many gastrojejunal ulcers require surgical treatment, a formidable procedure which is associated with an excessively high mortality

If partial gastric resection is to supplant gastroenterostomy, it must fulfil two requirements The mortality of the operation must not be higher than that of gastroenterostomy, and the incidence of re-

current ulcers must be lower than that observed in gastroenterostomy. In two series of cases reported from the Mount Sinai Hospital the mortality from partial gastrectomy was but 1.5 per cent, as compared with the 2 to 3 per cent mortality from gastroenterostomy. Thirty-four per cent of the gastroenterostomy cases at the same hospital developed gastrojejunal ulcers within five years after the operation. In contrast, but seven per cent of a series of eighty-two cases of gastric resection suffered recurrent ulcers. Since these two series of results were obtained by the same surgeons and in the same hospital they may be considered reliable for comparison and show a distinct advantage of partial gastrectomy over gastroenterostomy.

Gastric resection should be extensive enough to produce a marked lowering in the gastric acidity and in 66 per cent of Dr Lewisohn's cases complete anacidity was produced. Pylorotomy does not produce a significant lowering of the gastric acidity of a degree sufficient to give any better results than those obtained from gastroenterostomy. Ulcers should not be excised locally since the scarring and contraction following such a procedure interfere with peristalsis and lead to difficulties.

The results from partial gastric resection for chronic duodenal ulcer are extremely gratifying and the great majority of patients are restored to complete health following recovery from the operation.

Dr Arthur W. Allen in discussing the paper agreed with Dr Lewisohn in believing partial gastrectomy to be the operation of choice in the surgical treatment of nonobstructing duodenal ulcer. Gastroenterostomy has not been successful in relieving the symptoms of duodenal ulcer. Particularly is this true in the cases which bleed profusely years after the performance of gastroenterostomy. A recent analysis of the cases at the Massachusetts General Hospital showed but a five per cent incidence of jejunal ulcer following gastroenterostomy.

Gastroenterostomy still has a place in the treatment of elderly individuals with marked scar tissue contraction at the pylorus (which not infrequently follows prolonged medical treatment). Obstruction is relieved and there is rarely an occurrence of gastrojejunal ulcer in these cases.

Dr Charles G. Mixer stated that surgical treatment was but an incident in the course of the disease of duodenal ulcer although the resection of a sufficient amount of stomach to cause gastric anacidity may effect a cure in many instances.

STAFF MEETING OF THE ST ELIZABETH'S HOSPITAL

On January 3 at the staff meeting of the St. Elizabeth's Hospital Dr John A. Kolmer, Professor of Medicine at Temple University School of Medicine, and director of research at the Institute of Cutaneous Medicine, spoke on "Infection Immunity and Vaccination in Infantile Paralysis." Dr Joseph Stanton, chief of staff of the hospital, presided.

Dr Kolmer pointed out that the term "acute anterior poliomyelitis" is preferable to "infantile paralysis" since the disease is not confined to children or infants and only a small percentage of cases develop paralysis.

The majority of investigators think that a filtrable virus is the etiological agent of the disease, although Dr E. C. Rosenow of the Mayo Clinic believes that certain strains of streptococci are the responsible pathogens. Although streptococci can be recovered from a large percentage of the cords of fatal cases of the disease, Dr Kolmer believes that they are secondary and terminal invaders. The virus has never been cultured on lifeless media, although it has recently been propagated through six generations on tissue cultures thus suggesting the possibility of an improvement of the vaccine. The fact that poliomyelitis is a virus disease suggests that it may be successfully vaccinated against, since most virus diseases produce lasting immunity by one infection.

The virus usually enters the body by way of the nose and upper respiratory tract, although certain milk-borne epidemics have suggested that entry may occur through ingestion and invasion of the gastrointestinal tract. Experimentally it has been impossible to infect the macacus rhesus monkey by feeding the virus, although there is some evidence that other species of monkeys may be infected in this manner.

The mode of transmission of the disease still remains a mystery although Dr Kolmer believes it to be carried by normal immune adults and not by children. If this is true the prevention of the congregation of children during epidemics is not so important as prevention of the assembling of adults. The seasonal incidence of poliomyelitis is at its peak between the months of May and August, suggesting that an insect vector may be of importance in its conveyance. There is no positive proof of this supposition however.

The incidence of the paralytic type of poliomyelitis is very low and it is now believed that the disease is widespread and that most cases recover without paralysis. Prevention of the disease becomes of prime importance, when the marked rise in the incidence of paralytic and fatal cases occurring during epidemics is considered.

Immunity is usually conferred by one attack of the disease although some fifteen cases which have developed a second attack are reported. The only antibody discovered is known as a "neutralizing antibody." When active poliomyelitis virus is mixed with blood serum containing this antibody incubated and subsequently injected into the brain of a monkey it fails to produce the disease, since its activity is apparently neutralized by the said antibody. This method is the only means at present known which enables the determination of the presence or absence of the neutralizing antibody in the blood stream. Due to the fact that the macacus

rhesus monkey is the only animal known to be susceptible to poliomyelitis, it must be used for this test, which makes the determination of immunity and susceptibility an extremely costly matter. Other methods such as complement fixation, precipitin reactions, colloidal gold reactions, and skin tests have all failed, however.

Tests for this neutralizing antibody have shown that about eighty per cent of newborn children have passively acquired it by transplacental passage from the mother, and that this passive protection has completely disappeared by the end of the first year of life. Of children one to four years of age, fifty-eight to one hundred per cent (depending upon whether determinations are made upon city or rural populations) have been found to be without the antibody, and therefore susceptible to the disease. Between the ages of five and fourteen years, forty-six per cent of individuals are without the antibody, but after the age of fifteen years only twenty-five per cent of the population fail to show protection. These results indicate that the majority of persons contract the disease during childhood, and recover without residual paralyses.

Of 126 cases recovering from paralyzing attacks of poliomyelitis, 34.9 per cent failed to possess the neutralizing antibody in their blood serum. It is, therefore, assumed to be possible to have immunity to the disease without the presence of the antibody in the blood stream, suggesting that the true immunity is a tissue immunity and that the presence of antibody in the blood stream is merely a reflection of this more fundamental mechanism. Dr. E. W. Schultz of Stanford University Medical School has reported instances of monkeys which developed the acute infection in spite of the presence of the antibody in the blood stream. This report threatens many of the beliefs and hypotheses held relative to the disease, and requires investigation.

Vaccination against poliomyelitis has been the subject of a vast amount of investigative work. In 1910 Flexner found that subcutaneous injections of poliomyelitis virus into monkeys produced immunity to subsequent intracerebral virus injections. Some of these animals developed paralyses before immunity was acquired, however, and the method was deemed too dangerous to be applied to human beings.

It is impossible to produce immunity to a virus disease with a vaccine of dead or attenuated virus (Rabies vaccination may be a possible exception). Dr. Kolmer has developed a vaccine by treating the poliomyelitis virus with sodium ricinoleate. Such vaccine contains active virus, as determined by intracerebral inoculations in monkeys. The vaccine is administered subcutaneously in three divided doses at weekly intervals.

Of forty-two monkeys so vaccinated, ninety per cent developed immunity, as determined by sub-

sequent intracerebral injections of active virus. Only one of these animals developed a paralysis, which, however, was very mild. Of a control group of forty-two animals injected subcutaneously with untreated virus, two developed paralyses.

It is possible that the virus used in experimentation, and in the production of the vaccine, has been attenuated for human beings by its long series of passages through monkeys.

Dr. Kolmer first utilized his method of vaccination on himself and members of his family. No ill results were experienced and he injected a series of twenty-seven cases, determining production of immunity by means of the virus neutralizing test. Eighty-four per cent of the cases showed presence of the antibody in the blood stream following vaccination. Repetition of the tests one year later demonstrated persistence of the antibody in eighty per cent of the cases. Except for mild local reactions, none of the twenty-seven cases developed ill results from the vaccination.

Between April and October of 1935, 10,725 children were vaccinated with ricinoleated vaccine. Nine per cent of these showed mild local reactions, one to two per cent developed mild constitutional reactions with fever and vomiting. Twenty-six cases developed abscesses at the site of injection. These abscesses were due to the use of contaminated lots of vaccine, an eventuality guarded against in the future by the addition of one part in eighty thousand of mercuric nitrite to the vaccine at the time of preparation. There have been no allergic manifestations, no cases of myeloencephalopathy, or of lymphocytic chorio-meningitis in any of the patients vaccinated.

Nine of the children vaccinated developed paralyzing attacks of poliomyelitis during the course of injections. These misfortunes have caused doubt on the part of some workers as to the safety of the vaccine. All these cases developed between the eighth and fourteenth days after the first injection, some had received two injections, but none had been given the third. Dr. Kolmer believes that these cases were due to infection contracted before the vaccination, and that they were in the incubation period of the disease when vaccination was begun. It is possible that the administration of the vaccine to children in the incubation stage of the disease may increase the severity of the attack, due to the production of a transient so-called "negative phase" of immunity. He does not believe infection was caused by the vaccine.

Investigations are at present directed toward transmission of the disease to animals other than the monkey, in developing a more acceptable test of susceptibility than that in use at present, and in determining the efficiency and safety of vaccination with ricinoleated vaccine.

Dr. W. Lloyd Aycock, in discussing the paper, stated that neutralization of poliomyelitis virus by blood serum is an indication of previous ex-

posure to the disease and shows some degree of immunity. Neutralizing substances can be induced in the blood stream by a series of subcutaneous injections of active virus but this does not necessarily produce complete immunity to intracerebral or intranasal injection of the virus. Only sixteen per cent of monkeys receiving large subcutaneous injections of active virus develop the disease.

Dr Aycock questioned the value and safety of human vaccination against poliomyelitis. Determinations of virus neutralizing substances in the blood serum before and after vaccination have failed to show any great value in vaccination. Of a series of twenty-eight cases forty-three per cent possessed neutralizing antibodies in the blood before and seventy-three per cent following vaccination. In the control group of thirty-six cases, forty-one per cent possessed the antibody before, and sixty-seven per cent after the lapse of a period of time identical to that between tests in the first group. It is thus seen that there is only a two per cent advantage to vaccination, a very small one especially when the danger of the process is considered.

In discussing the cases of poliomyelitis developing after vaccination, Dr Aycock pointed out that the incubation period of the disease in the monkey is usually seven to fourteen days. The human cases appeared between the sixth and fourteenth days following the vaccine injections. It is more probable that the injections caused the infections than that they were contracted prior to the vaccinations. Modification of the virus results only in prolonging the incubation period and does not alter the severity of the disease.

The incidence of poliomyelitis in the United States is one case per thousand population. Approximately twenty thousand children have been vaccinated with ricinoleated virus to date and at least fifty per cent of these have previously acquired immunity as indicated by the virus neutralization test. Thus ten thousand susceptible children have been vaccinated. Of this group twelve have developed the disease after vaccination. The incidence of postvaccinal infection is thus seen to be higher than the usually observed rate in unvaccinated children.

The prevention of poliomyelitis depends upon the development of a safer and better method of vaccination and upon perfection of some method of determining susceptibility to the infection.

Dr Hans Zinsser emphasized the fact that there is no evidence that immunity can be produced by the inoculations of small amounts of dead virus. It is possible that attenuated virus may produce immunity but attenuation is difficult to achieve and more particularly to control. In his own work in herpes immunity which is closely analogous to poliomyelitis, it was shown that the development of immunity followed only when some sort of reaction to living virus was evident. In poliomyelitis evidence available from animal inoculation seems to

show that even with living virus it requires a large number of injections into or under the skin to produce a protection against subsequent intranasal infections. The mere fact that a large majority of individuals subcutaneously injected with a poliomyelitis preparation do not develop the disease means relatively little since we know that in the analogous problem of rabies immunization only a small percentage of susceptible animals will come down, even when large amounts of living virus are subcutaneously administered.

The incidence of poliomyelitis following the infection of Dr Kolmer's vaccine is low but this may not be because the virus is modified by ricinoleate, but because it is difficult to produce poliomyelitis by the subcutaneous route. Dr Zinsser does not believe that living poliomyelitis virus should be injected subcutaneously into children even though it is known that this but rarely causes the disease and may cause immunity. He believes that lines of investigation thoroughly worked out in a preliminary way on animals should follow those of serovaccination and increased efforts at tissue culture, so that higher concentrations of virus may eventually be obtained thus making immunization with dead virus a possible prospect.

Dr John F. Casey told of vaccinating himself and his children with Dr Kolmer's vaccine and of his belief in its safety. The cases developing the disease following vaccination occurred in communities in which the incidence of poliomyelitis was much higher than the usual one per thousand which causes doubt as to the responsibility of the inoculations for the development of the disease.

REPORT OF COMMITTEE ON VACCINATIONS IMMUNIZATIONS AND EXAMINATIONS OF WELL BABIES AND PRESCHOOL CHILDREN

A meeting of the committees from the Middlesex South, Suffolk and Norfolk District Medical Societies in regard to the organization of the medical profession in Boston to furnish immunization against diphtheria, and vaccination to the public at a fee commensurate with the individual's ability to pay was held at the rooms of the Massachusetts Medical Society on Wednesday December 4 1935 at 4 00 P.M.

The following committee members were present
Middlesex South District—Dr John F. Casey Dr Leo G. Rondeau, and Dr Wilfred G. Grandison.

Suffolk District—Dr Channing Frothingham and Dr John J. Todd

Norfolk District—Dr Henry Landesman Dr David L. Lioberger and Dr John B. Hall.

In addition to the committee members Dr Sumner H. Remick, President of Middlesex South Dr Robert L. DeNormandie President of Suffolk Dr Laighton F. Johnson President and Dr Frank S. Cruickshank, Secretary of the Norfolk District Medical Society were present.

It was the unanimous opinion that doctors should

BOOK REVIEWS**The Pathology of Internal Diseases** Second Edi-
tion William Boyd 904 pp Philadelphia Lea &
Febiger \$10.00

The second edition of this presentation of path-
ology from the clinical angle, particularly the med-
ical, will continue the well deserved popularity of
the first edition. Written in Boyd's lucid and pleas-
ant style, well illustrated and adequately supplied
with references, it serves as a thoroughly satisfac-
tory reference book for the practitioner. The dis-
eases are considered in relation to the organ in-
volved and an excellent correlation of pathology
and symptomatology is given. The section on
rheumatic fever is excellent although the reviewer
feels that the discussion of etiology should be more
adequate, and Rinehart's work on the supposed re-
lationship of scurvy to rheumatic fever perhaps is
given more prominence than it deserves. The dis-
cussion of pulmonary tuberculosis is very clear and
satisfactory. The discussion of liver pathology is
particularly well presented. Under the thyroid, the
presentation of Riedel's struma is not balanced by
its more important counterpart, the struma lympho-
matosa. The section on the etiology of Hodgkin's
disease is clear and fairly presents the different
viewpoints.

These scattered notes hardly indicate the high
standard of excellence maintained in the whole
volume.

The Medical Record Visiting List for 1936 Pub-
lished by William Wood & Company in three sizes,
\$1.75 to \$2.50 each

This little volume, published annually, has been
revised to supply information relating to emergen-
cies, and contains sections for recording special
treatments. It is especially adapted to keeping the
physician's financial daily records.

NEW ENGLAND SURGICAL SOCIETY

ONE HUNDRED UNTREATED CANCERS OF THE RECTUM*

LY ERNEST M. DALAND, M.D.,† CLAUDE L. WELCH, M.D.† AND IRA NATHANSON, M.D.†

THE success of the treatment of any disease is measured by a study of the cases treated in comparison with a group which is untreated. It is essential to study the natural history of cancer to determine the benefits of treatment. Although the importance of such a study seems obvious, it is surprising that very little such information has been presented in the literature.

The only adequate series of untreated cases of cancer of the common types in other countries are presented by the British Ministry of Health. Large series of cancers of the breast, uterus, rectum, tongue and mouth, and esophagus have been studied by this committee.^{1,2,3} Untreated cancer of the breast has been studied in Switzerland by Lukac.⁴ In this country a start has been made by a survey of one hundred untreated cancers of the breast by Daland,⁵ but other groups of cancer have not been analyzed.

Cancer of the rectum is one of the most common types of malignant disease. We have chosen it for this discussion because of the comparatively large number of untreated cases that we have been able to observe, and because we have also been able to see the results of treatment by other methods in the same hospitals.

TABLE 1
DISTRIBUTION OF UNTREATED CASES

Hospital	No. Cases	Years
Collis P. Huntington Memorial	44	1912-35
Pondville Hospital	41	1937-35
House of the Good Samaritan	10	1912-32
Massachusetts General Hospital	5	1910-32
Total	100	

These one hundred cases have been taken from the Collis P. Huntington Memorial Hospital, The Pondville Hospital, The House of the Good

Samaritan and the Massachusetts General Hospital. The three hospitals first mentioned are cancer hospitals and all cases in their record files have been considered. The Massachusetts General Hospital is a hospital for acute illnesses but we were able to find five who died without treatment. All records have been checked very carefully, letters have been written to hospital physicians and relatives, we have reviewed the death certificates and feel certain that none of the patients mentioned in this series ever received any treatment. A microscopic diagnosis of carcinoma was made in thirty-five cases, either from biopsy or postmortem material.

The length of life, the comfort of the patient and the comfort of his family are the only measures of comparison between treatment and non-treatment. The length of life can be accurately determined and furnishes a valuable index of the benefits of various types of treatment. The comfort of the patient, on the other hand, cannot be reduced to figures, but there is hardly a more miserable man alive than one with an advanced cancer of the rectum. This is so well realized that many surgeons feel that desperate chances should be taken to attempt a cure by radical surgery rather than let the patient go on to the advanced stages. Not only is the untreated patient ever in distress, but he is a source of trouble to his whole family. A well functioning colostomy opening is much easier to care for than an incontinent rectum.

All of our data have been computed from the onset of the symptoms which we interpret as due to the disease. A change in bowel habits is the criterion we have used in determining the date of onset of symptoms. The actual beginning of the cancer must have antedated the first symptom.

Why were these patients untreated? We can not give an exact answer. Some patients were too old or in too poor condition. Some were deterred by the thoughts of a colostomy or by the magnitude of the radical operation. The disease in some patients when first examined was too advanced for treatment. In still others, the medical advice before admission to the hospital was poor because of inadequate rectal examina-

tion, prejudice against colostomy or lack of faith in surgery

There were fifty-six males and forty-four females in our series. The youngest was thirty-two and the oldest ninety-two. The average age at onset of symptoms was 59.6 years. The median age was fifty-nine years,—that is, there were as many under fifty-nine years as there were over it. Table 2 shows the age distribution by five-year periods. The cases are fairly

in one patient who lived forty-nine months. The females lived slightly longer than the males, the median length of life was sixteen and fourteen months, respectively. The accumulated death curve of all untreated cases is shown in figure 1.

COLOSTOMY

In order to determine whether performing colostomy prolongs life, we have analyzed the

TABLE 2
AGES AND DURATION OF LIFE FROM ONSET OF SYMPTOMS

85-89	1	19	1	14		
90-94	1	23				
100 All died of Cancer			80 All died of Cancer		32 All died of Cancer	
Median length of life from onset—14 months			Median length of life from onset—14 months		Median length of life from onset—15 months	
Average length of life from onset—17.2 months			Average length of life from onset—16.9 months		Average length of life from onset—18.8 months	

evenly distributed between the ages of forty-five and seventy-five. Twenty per cent of the cases were found outside of these limits. Table 2 also shows the duration of life from onset of

records of eighty patients in whom colostomy was done without any other treatment. Sixty-five of these were from the Pondville Hospital and fifteen from the Collis P. Huntington Memorial Hospital. Fifty-nine were males and

FIGURE 1 Duration of life in 100 untreated cancers of the rectum

symptoms to death in each age group. There is no significant variation in the length of life in the various groups. The average length of life was 17.2 months. The median length of life was fourteen months. One patient died one month after onset. The longest duration was

FIGURE 2 Duration of life in 80 colostomies compared with 100 untreated cancers of the rectum.

twenty-one were females. The average age at onset was 58.1 years, the median age was fifty-eight. All of these patients died of cancer, the length of life varying from two to fifty-six months after the onset of symptoms. One quarter of these patients were dead in seven months,

one half in fourteen months, three quarters in twenty four months after onset of symptoms. The median length of life from onset to treatment was seven months, from treatment to death, five months and from onset to death four teen months. The average length of life following colostomy was six months, the average from onset to death was 16.9 months.

Table 2 shows the average duration of life in the different age periods. The youngest patient was thirty two and the oldest eighty eight. It will be observed from the table that the age of the patient bears no relation to the duration of the disease. Figure 2 shows that patients who have had colostomy done live no longer than the untreated cases, in fact the two curves of duration of life are practically identical. The comfort of the patients then is the only consideration in performing a colostomy.

We have included in this series twenty four patients who have come to us after having had a colostomy done elsewhere. Of the fifty six others in whom we advised colostomy there were seven strictly operative deaths, a mortality of 12.5 per cent. Some of these operations were done in local hospitals, but the majority were done at the Pondville Hospital or the Huntington Hospital.

COLOSTOMY AND X RAY

The effect of x ray treatment to the local lesion in connection with colostomy has been studied in another group of thirty two cases. All but three of these patients were treated at Pondville. The amount of x ray therapy in these cases varied from 300 r to 2800 r units. In the majority of cases the intention was to relieve pain in the pelvis. In very few was the dosage sufficient to expect any change in the tumor. It is not fair to conclude from this small series of partially treated cases that x ray therapy is of no value. However, in these clinics we have not been impressed with its value in any case except for the relief of pain. It is of some benefit for this purpose in instances.

This series is closely comparable with the colostomy group. These were twenty three males and nine females. The average at onset was fifty seven years, the median age the same. All of these patients died of cancer, half of them being dead at fifteen months after onset of symptoms. The length of life from onset varied from four months to forty five months. The median length of life from onset to treatment was seven months, from treatment to death, eight months and from onset to death, fifteen months. It is possible that the increased median length of life from treatment to death, compared with patients in whom colostomy only was done was due to the fact that x ray therapy was used in the patients in whom the expectation of life seemed longer. Also this group represents only those who survived the colostomy

operation, for the operation was always done before x ray treatment was given. The average length of life following colostomy and x ray treatment was 9.5 months, the average from onset to death 18.8 months.

Table 2 shows the distribution by age groups and the respective length of life. The numbers in each group are too small to be significant statistically. The youngest patient was thirty eight and the oldest seventy six. Figure 3

FIGURE 2. Duration of life in 52 patients having colostomy and x ray treatment, compared with those having colostomy alone.

shows a close similarity in the curves of the patients treated by colostomy and x ray and those in whom only a colostomy was done.

RADICAL OPERATION

The group of forty two radical operations here studied represents all the patients who came to the Huntington Hospital between 1912 and 1930 who were referred elsewhere for resection. None of the operations were done at the Huntington Hospital as the hospital is not equipped to do major abdominal surgery. The operations were done in nineteen different hospitals, ten of which are in Boston. End results were obtained in all cases.

There were twenty five males and seventeen females. The youngest patient was thirty six and the oldest was seventy four. The average age at onset of symptoms was 51.5 years, the median age was fifty-six years. The median length of life from onset to treatment was eight months. The median length of life from treatment to death was twenty seven months. Table 3 summarizes this series by age groups. Of the forty two patients in whom the radical operation was done eleven died as the result of the operation. This gives an operative mortality in the nineteen hospitals of 26.2 per cent. Thirty three per cent were alive five years after onset of symptoms. Two patients died of intercurrent disease without recurrence within the five year period. This gives us forty cases on which to base our percentage of cures. Twelve patients (30 per cent) were alive and free from disease for five years after operation. Seventeen patients died with cancer.

Figure 4 shows the death curve of the radical resections in comparison with that in the untreated cases. Figure 5 shows the length of life after operation in patients who had colostomies performed and those who had radical resections done.

TABLE 3

AGES OF RADICAL OPERATION CASES AND RESULTS

colostomies performed and those who had radical resections done.

SEX

In the four groups studied above there were 254 cases. Three of the hospitals from which this material was obtained admit both men and women. The House of the Good Samaritan admits women only. Hence, in studying sex incidence, we must eliminate the ten cases from

FIGURE 4 Duration of life in 42 radical resection cases compared with the untreated group

that hospital. Of 244 cases, 163 were males and 81 were females,—exactly a 2:1 ratio.

It is generally accepted that cancer of the rectum is more common in males than in females. David⁹ says that rectal cancer involves the two sexes almost equally but there is a slight preponderance in the male. In Gant's⁷ series fifty-two per cent were males and forty-eight per cent females. Pack and LeFevre⁸ found 69.7 per cent were females. Miles⁹ quotes a 6:5 ratio between males and females. In the

group where colostomy alone was possible, Gabriel¹⁰ found a 3:1 ratio for males, Rankin, Barger and Buie¹¹ found about the same ratio.

The British Ministry of Health³ states that the operability in four published series was much higher for women than for men, and Rankin, Barger and Buie agree that this is so.

FIGURE 5 Duration of life after operation in colostomy and radical resection cases

This may explain the reason why the female ratio is so low in the cases submitted to colostomy in the series mentioned above.

In our own study we have found that in all groups, within the limits of error, the males hold almost exactly the same 2:1 ratio, whether the patients are treated or not. This is shown in table 4.

TABLE 4

Total	163		81		244

DISCUSSION

Reports of the British Ministry of Health show some variation in the different studies that have been made of untreated cancer of the rectum. In Report No. 33¹, 887 cases are analyzed with a median duration of life of twenty-one months from onset of symptoms. In a later report (Report No. 66)³, comprising ninety-five cases, the median duration was 8.5 months. We are unable to explain the wide difference in their two series. Our median length of life was fourteen months, about midway between the two British series.

We agree with the following statement made by the British Ministry of Health:

"It will be seen that, either there is no significant relation between age at onset and duration of, at the least, these data are not numerous

enough to establish it. It should be remarked that the mean duration is so small in comparison with the average duration of life from any age within the range (the average after lifetime at the age of seventy exceeds $8\frac{1}{2}$ years in both sexes) that the decrease of normal expectation of life with age is unimportant in comparison with the difference between the expectation of the untreated patient and that of a normal person at any age within the range."

Hayden and Shedden¹ have analyzed all the cases treated by radium at the Collis P. Huntington Hospital. They concluded that patients treated by radium alone lived no longer than if untreated, that the patients in whom colostomy has been performed lived four months longer, on the average than if untreated and that the patients treated by colostomy plus radium lived four months longer than if colostomy

they were untreated, treated by colostomy, or by radical resection.

4 The median age of the patients subjected to radical operation was three years less than in the untreated group.

5 The median delay from onset to treatment was eight months in the radical cases and seven months in the colostomy cases.

6 In this series the operative mortality rate for colostomy was 12.5 per cent and for radical resection 26.2 per cent. The five-year curability was 30 per cent. We consider these results a fair cross-section of the results being obtained by surgeons in this community during this period, but they are by no means the optimum results that may be obtained.

CONCLUSIONS

Patients suffering from cancer of the rectum will live as long if no treatment is given as they

TABLE 5

	Untreated	Colostomy	Colostomy and X Ray	Radical

5 Year Cures	—	—	—	30%

alone had been done. Their group of cases in which colostomy alone was used was small; hence, we believe, the difference between their figures and ours.

The operation for cancer of the rectum done in this series was, for the most part, either the two-stage operation advocated by Jones or the one-stage operation recommended by Jones and Miles. We cannot compare our results with those published by Jones¹² in regard to operative mortality or curability because we do not know the percentage of operability in our group.

SUMMARY

1 The median duration of life in 100 untreated cases of cancer of the rectum was four teen months. Untreated patients lived from one to forty nine months after onset of symptoms.

2. Colostomy (80 cases) or colostomy combined with x ray treatment (32 cases) did not prolong life appreciably in comparison with the life duration of untreated cases.

3 There was a two to one predominance of males over females in the cases studied, whether

will if a colostomy is performed and nothing further done. However, they are much more comfortable during the fourteen months they have to live if they do submit to colostomy. X ray treatment combined with the colostomy operation may aid in relieving pain.

The operative mortality for the radical resection of the rectum in one or two stages is low enough to warrant radical surgery when there is probability that the growth can be removed. The duration of life is much longer than in the other groups and the patients are free from symptoms during this increased span of life. There is a thirty per cent possibility of cure for at least five years.

DISCUSSION

DR CLAUDE WELCH Since Dr Jarvis has already spoken of propagandizing the medical profession, you may excuse a younger man if he uses the same terms in speaking of cancer of the rectum. The value of Dr Daland's paper, it seems to me, lies in the fact that it points out very concretely the value of radical operation in any case of cancer of the rectum.

In speaking of that fact, it would have been of great advantage if we had been able to present a curve of radical operations in which there were no operative mortalities and one hundred per cent cures. We feel that our figures do not represent the optimum, by any manner of means. For example, Dr Jones' figures of eleven per cent mortality in his private patients and Dr Lahey's results which were reported here last year of slightly over eight per cent in his private patients, make one realize that we have not presented these data as best we could to tell the medical profession that operation is desirable.

In order to see whether there has been any improvement in operating on these patients, I have reviewed the cases in the Massachusetts General Hospital from the year 1930 to 1934 inclusive. During this five-year period there was an operability rate of sixty-three per cent. That is a figure we could not include in our paper because we could not obtain it from the Huntington Hospital records.

This means that sixty three per cent of all patients admitted to the wards of the Massachusetts General Hospital or Tumor Clinic were subjected to radical operation before they left. There were, during this five-year period, one hundred and seven radical operations done by twenty two different operators, all the way from Dr Daniel Jones down to the surgical resident.

The operative mortality in this large group was 14.1 per cent over this period. During the last year, 1934, there were twenty nine operations done, with one death. The operability rate this year was seventy per cent. These results contrast very favorably with the slightly over twenty-six per cent mortality that Dr Daland has reported in his cases. I think as soon as the medical profession realizes that the mortality from operation is not so high as it has been led to think previously, and that the number of five-year cures have increased remarkably, we shall gain in the treatment and control of cancer of the rectum.

PRESIDENT JOHNSON Discussion of this paper will be opened by Dr Lyman Allen.

DR LYMAN ALLEN, Burlington, Vt. I have not very much to add to this discussion. I looked up the number of cases of cancer of the rectum we had had in our two hospitals in Burlington in the last five years, but I did not receive notice that I was to

discuss this in time to follow them up fully. The follow up part of it which I tried to do was very unsatisfactory, which leads me to think that most of them have already passed beyond where we can succeed in following them up.

I found, however, that in five years in these two hospitals, of about two hundred and fifty beds, we have had only thirty four cases of cancer of the rectum. Ten of these had no operation, whatever, and of the ten, five died while they were in the hospital, which means they were admitted in the last stages probably, too late to do anything. Twelve of the thirty four had colostomies and we had no hospital deaths in that number.

With thirty two out of thirty four with either no operation or colostomy only, it means either that the cases were seen too late to make radical operation worth while, or that the patient refused radical operation. It is probably partly one and partly the other.

Five had treatment by radium and one of these cases later had a colostomy. There was no death in that list of five cases, again, evidently late cases. Only seven had radical operation and of these seven, three died, forty two per cent. One was a cautery operation, one was a perineal operation, and five were two stage operations. The deaths all came in the two-stage operations.

One of those radium cases, the only one I could follow, lived three years and a half, at least. The colostomies lived for varying times fifteen months, to two years. As I have said, many of them I could not follow. Our youngest patient was thirty two and our oldest was seventy nine.

So cancer of the rectum is not necessarily a disease of even middle age. There were twenty two males and twelve females, which is practically the proportion given here in this paper.

It has been suggested that a complete rectal examination should be made on all (the population of the country). Obviously, it is impossible to do that, but the suggestion was made in a recent paper. I do think we might say that a rectal examination should be made and could be made upon every patient that comes to us for a full check up, as they call it. I do not think that is asking too much.

If that were done, we should get a larger percentage of early cases. As it is, since there are no early symptoms, the patient has had cancer of the rectum for some time before he presents himself to us.

In my opinion, radical operation is indicated whenever the patient will allow it. The mortality is high in the ordinary operator's hands, but I think if I had cancer of the rectum, I should welcome a high mortality.

PRESIDENT JOHNSON Dr Walter Seelye

DR WALTER C SEELYE, Worcester, Mass. I am very much interested in the mere fact that Dr Daland has been able to assemble one hundred cases of untreated cancer of the rectum. I think it is a remarkable thing to have followed up so many cases and have statistics as a criterion upon which to base operative treatment.

As has been said here and emphasized so much, the mortality of cancer of the rectum by radical operation is high, but the tables which have been shown are very interesting in that they bring out the fact that even with the high mortality, high operative mortality, you have a five-year cure of thirty per cent in Dr Daland's series, and thirty four per cent, I believe, in Dr Jones' series of five-year cures.

All that goes to show that in the first place technique can be improved to reduce the operative mortality, and in the second place, the cases of five-year

ture can be markedly increased if the length of time between beginning of symptoms and operation is reduced.

There is one thing that has impressed me very much in going over this subject, as Dr Daland has presented it, and as had been presented in other papers of Dr Jones. They emphasize an average of eight months' duration, and it is interesting to see that all statistics agree so closely in just about the eight months period from onset of symptoms to the time the patient is brought in for treatment.

The only way I can see to shorten this interval of eight months is by a propaganda of education first, to physicians in general to recognize early symptoms of cancer of the rectum and secondly the same education carried across to the general public to become mindful of the possibility of cancer of the rectum when they have symptoms of bleeding or mucous discharge from the rectum or change of bowel habits for which they seek advice.

That, I feel also could well be taken up by the medical societies by sending out leaflets or reprints to all the men of each district society to give them warning in their general examination of patients to be mindful of the possibility of cancer of the rectum in dealing with intestinal symptoms of the patients who consult them.

DR. EDWARD L. YOUNG, JR., Boston, Mass. There are two cures Dr Daland did not give us. One I think he never can give us and one I wish he would. I wish some day he would give us a cure of the difference between the cures in those cases of radical operation where there was no evidence of spread of the disease and in those cases where there was a spread of the disease and nevertheless the local growth was removable.

I think all of you who have seen the end stages of cancer in the pelvis whether it comes from rectum, cervix or bladder will feel as I do that it is a terrible way to die. I believe that cancer of the rectum should always be removed regardless of whether there is a liver metastasis, provided the local growth is removable because the second curve which he can never give is the difference even though length of life was not prolonged between the comfort in dying without the growth and with it.

DR. FRANK H. LAHEY, Boston, Mass. I dislike to repeat previous statements relating to cancer but we have definite convictions on this subject. I think that everyone who has had experience with cancer of the rectum because of the depressing reaction to it on the part of patients, is duty bound to speak on the hopefulness of the subject. I wish to add my words to what Dr Welch has said that it is a hopeful lesion from the point of view of curability also that the operability can be much increased.

Lyman Allen sitting beside me asked me what our mortality was. When our operability was around fifty-four per cent, our mortality was eight and a quarter per cent, but we have increased operability to seventy per cent, with the result the mortality has gone to about 12½ per cent. We must not, as Dr Young said be too proud of our mortality rate because, we must widen this operability rather to make these people comfortable than narrow it to make our result appear well. If a radical removal is done and they die of liver metastasis, they are infinitely more comfortable than with local growths.

Carcinoma of the rectum is a relatively benign growth. Forty-six per cent of all our cases that have had the radical operation are alive and well over five years. When you have a lesion that can

give such high percentage of relief over five years then I believe it is your duty to get this fact before the public and dispel this depressed attitude which is in the mind of the public regarding the hopelessness of cancer of the rectum.

DR. EDWARD H. RISLEY, Waterville, Me. I would like to say something about the treatment of colostomies. I think we all know that it is very difficult to get some patients to consent to colostomy. They dread the thing. They have heard about the difficulties in its care and it is often very hard to persuade them to consent to it. Therefore any detail we can add in the aftercare of our colostomy patients is very much worth while.

For the last two or three years we have been doing all our colostomies in the midline regardless of whether they are inoperable cases for two reasons. One because we thought it shortened our period of operation somewhat, and because it is so much more convenient for the patient to handle a colostomy in the midline.

The detail that we have worked out which is being much appreciated is very simple. The ordinary textbook illustration is of a patient handling an extensive colostomy an irrigating can with an irrigating tube, the patient sitting on a stool with a large sheet of heavy rubber wrapped around him draped into a pail.

That is very abhorrent to most people. We have found lately that if we provide our patient, before he goes out of the hospital with a small stiff rubber apron, which ties around the waist with a rubber strap and is more or less pear shaped it draps down into the toilet. The patient sits on the toilet in the normal position.

The colostomy belt is simply strapped around the waist below the colostomy or if the colostomy is very protruding a little hole is made in the rubber and it fits tight to the body over the colostomy. A little button can be put on so that it forms a cone. The patient can have his normal stool without soiling his person and if he has to irrigate also without soiling his person or the toilet.

This is a simple thing but I have had a number of patients who expressed their appreciation of this little gift that I always present to them before they leave the hospital.

DR. LELAND S. MCKITTRICK, Boston, Mass. I do not like to prolong this discussion and I will only speak for a minute. I have been very much interested in this paper of Dr Daland. I cannot add anything to it, but I want to stress one or two things which he said.

The first is in relation to colostomy. Whether his figures would be the same in a larger series of cases makes no difference. Apparently the patient who has a colostomy for inoperable cancer of the rectum does not live any longer than the patient who does not. Those of us who have been rather intimately connected with terminal care hospitals, where patients come to die of cancer are interested in giving the minimum of discomfort rather than in increasing the length of life. I was much interested a few years ago to hear one of the better known English surgeons in the field of cancer of the rectum say that in their inoperable cases (their operability being between thirty and thirty-five per cent) they did colostomies and the local physician was able to keep the patients very comfortable from then on. I hate to admit that our men here cannot do the same thing.

A colostomy is no joke and I do not think we have any justification for doing a colostomy on a patient with incurable or inoperable cancer of the rectum unless we are going to relieve some specific symptoms which that patient has. A colostomy will

only partly relieve a patient's tenesmus. It will completely relieve the symptoms due to obstruction. Therefore, you must carefully evaluate the symptoms of which the individual patient is complaining before you advise for or against colostomy. I do not believe in a colostomy in anticipation of future obstruction, nor will the patient appreciate that. If on the other hand he has enough obstruction to be pretty uncomfortable, and if you relieve those symptoms, he will like you and like his colostomy.

I would like to say one more thing about a colostomy, too many times the general practitioner gets an improper impression from the patient with incurable cancer. The difference between a colostomy for curable cancer where the growth is removed, and a colostomy without the removal of the growth, is the difference between day and night. They must not be confused.

I was terribly distressed to hear Dr. Allen say he would like to accept a high mortality. I know that Dr. Allen might feel that way, but I know he has lots of friends, and I know he has lots of patients who would not feel that way.

I try very hard to follow all of my patients in definitely. I have been particularly interested in their reactions to a colostomy. I have felt that it was not quite fair for those of us who are well and

normal to pass judgment upon a colostomy but rather to leave this to those who are living with this handicap. When I see these patients bringing up their families, contributing toward their community life, and find them and their families happy, it is very hard for me to go all the way with Doctor Allen when he says that he personally would accept a high mortality in preference to a colostomy.

If I interpret Doctor Daland correctly he says that the young patient with cancer of the rectum lives as long as the older patient with the same condition. This is very important because most of us have had a difficult time in doing very much for young patients with cancer of the rectum. I believe that the reason for this is quite clear. As long as you and I think and talk in terms of a cancer age the average practitioner who sees one case of cancer of the rectum in four or five years will never think of the possibility of cancer in the young patient. In this group a diagnosis of cancer of the rectum is usually made only after the patient has lived long enough to prove every other diagnosis wrong. These patients, then, upon whom a diagnosis should be made at the time of the first visit lose most of their opportunity for cure in the delay which results from our talking in terms of cancer age rather than cancer symptoms.

DISTRIBUTION OF ACUTE HEAT EFFECTS IN VARIOUS PARTS OF THE WORLD*

BY GEORGE CHEEVER SHATTUCK, M.D.,† AND MARGARET M. HILFERTY, ED.M.‡

FOREWORD

INITIAL studies having been made of the distribution and probable causes of acute heat effects in the United States† (Shattuck and Hilferty 1932 and 1933), it seemed desirable to pursue the subject further and to see what could be learned of mortality and acute morbidity from heat in the world as a whole. Such information will make it possible to define more clearly than has yet been done the extent and relative importance of the acute effects of heat in various parts of the world and will serve as a basis for further studies of the causes and means of prevention of such effects in the localities where heat cases are sufficiently numerous to constitute a problem of importance.

There are several circumstances which render such an undertaking difficult. First, no reports are available for some of the places for which one would most desire them. Secondly, deaths from effects of heat being relatively few, some countries report them only as part of the total from external causes, as in the Abridged International List of the Causes of Death. Thirdly, as there are occasional years in which the number of deaths is many times greater than the

usual number, an adequate picture can be obtained only from records for rather a long series of years.

It is even more difficult to obtain statistics for morbidity from heat effects. Not being infectious, these cases are not reported to civil health authorities. Morbidity statistics are in hand, however, from two sources, namely, (1) reports of the health of armies and navies, and (2) hospital statistics from parts of Africa. Fortunately, there are "insolation" figures in almost all the army reports which we have seen, even those which list only about thirty causes of sickness. The Annual Report of the Health of the Army of Great Britain is an exception, but the Report of the Public Health Commissioner with the Government of India gives figures for the British Army there which are doubly welcome because of the scarcity of other information from India. We have been able to consult a smaller number of navy records. These army and navy records have the advantage of being practically complete as to cases and deaths, and figures are available as to the mean strength of the forces. However, in general, the deaths are too few to permit of analysis.

The reports of hospitals in certain parts of Africa and in the Far East are the only sources of information obtained from some of these localities.

SECTION I

MORTALITY RATES PER 100,000 BY COUNTRIES

A summary of the mortality statistics collected from various countries is given in table 1

*From the Departments of Tropical Medicine and of Vital Statistics of the Harvard School of Public Health.

†Sunstroke and allied conditions in the United States. *Am J Trop Med* 12: 223, 1932.

‡Causes of deaths from heat in Massachusetts. *New Eng J Med* 208: 319, 1933.

§Shattuck, George Cheever—Assistant Professor of Tropical Medicine, Harvard University Medical School. Hilferty, Margaret M.—Formerly Statistical Technician in the Department of Vital Statistics, Harvard School of Public Health. For records and addresses of authors see This Week's Issue, page 491.

The tabulations are of the years for which we have information from the various countries or parts thereof. The headings indicate (1) the total number of deaths from this cause, (2) the mean death rates from effects of heat, and (3) the ratio of males to females among the decedents. The mean death rates are given with the standard deviation of the mean based on the computed and not the Bernoulli standard deviation.

The number of deaths in the United States of America in thirty-three years, 1900-1932, is greater than the total of all the others here recorded. The average rate for the United States of America for this period is exceeded, however, by those for the Resident Foreign Community of Shanghai and for the Republic of Panama, and it is approached by the rate for Australia. (See italicized figures in table 1.) The Australian rate is based on mortality in the years 1908-1931. The average rate in the Registration Area of the United States is $1.78 \pm .39$ per 100,000 which does not differ significantly from the Australian rate of $1.49 \pm .18$. The next highest rates are found in Colombia and in Rio de Janeiro (Federal District), but neither of them is very well determined. Argentina, Canada, the Union of South Africa and Japan have rates of from 48 to 65. The European countries from which we have data except The Netherlands which has a rate of $.43 \pm .31$, show very moderate rates of less than .35 per 100,000. Only a quarter of the States in the United States of America Registration Area had rates as low as this.

A word of explanation is required about the figures for The Netherlands. The numbers of deaths occurring in each of the years 1916-1930 have been published*. The total is 443 of which 303 occurred in 1923. On this account, the mean rate for the period is not at all representative. Excluding 1923, the average rate for these years is 15, which gives a picture of the usual mortality from effects of heat. But this figure is falsely low and, on the other hand, when 1923 is included, the rate of $.43 \pm$ is misleadingly high. The rates being given by quinquennial averages from 1901-1916, one can obtain an average rate for the thirty years 1901-1930, and thus give less weight to the 1923 figure. Even so, the average rate, 25, is at least twice as high as it would have been without the 1923 experience. This is an extreme example of the difficulty in discussing death rates from heat.

DEATH RATES IN UNUSUAL YEARS

Certain years stand out as periods in which high rates were rather general. Chief among these is 1911, when England and Wales, Hun-

gary, Italy, Paris, Switzerland and the United States all had large numbers of deaths from heat. The rates differed greatly, being 36 in Italy, 149 in England, and 53 in the United States, but each was well above the normal. In England, the rate was the highest in the twenty-nine years 1902-1930. The 1911 rate in Italy, however, was exceeded in 1921 and in 1928. The year 1921 brought also a high rate for England and for the British soldiers in India (table 2). In 1928, the civilian mortality in Italy was most severe, and so also was the military morbidity in Germany and that of the French soldiers in Algeria. Elsewhere, the year was not unusual. In 1923, when the death rate in Holland was abnormally high, England experienced its second highest rate.

Inasmuch as our previous studies of heat effects in the United States showed that unusual mortality there was closely correlated with unusually high atmospheric temperatures continuing for several days at least, and because there is no reason to suppose that the normal habits of the people of Europe or of India were disturbed in the years above mentioned, it is highly probable that these unusually high death rates were caused by particularly unfavorable atmospheric conditions and that the chief cause was excessive atmospheric temperatures, perhaps, intensified by high humidity or low wind velocity.

COMMENTS ON SECTION I

The data in table 1 give but a fragmentary picture of the world-distribution and prevalence of deaths from heat. One may, however, draw the following inferences from the data.

(1) The proportion of deaths from heat in Europe and in the British Isles is much smaller than that in the United States.

(2) Canada has a decidedly smaller proportion of deaths from heat than has the United States.

(3) Apparently, there are few deaths from heat in Mexico City, the West Indies or Bermuda.

(4) The figures for Central America, for South America, for Africa and for Asia, permit of no generalizations. Some of the rates are notably low and others outstandingly high. The striking divergencies indicate the need for further data from these regions.

(5) The sex ratios shown in table 1, with few exceptions, indicate that deaths from heat are far more common in men than in women.

SECTION II

HEAT EFFECTS IN VARIOUS ARMIES AND NAVIES

Comparability. The morbidity rates for illness attributed to heat in various armies are shown in table 2. The figures are comparable only in a general way because neither the basis of reporting nor the years for which data are

*Statistiek van Nederland. Statistiek van de Sterfte naar den leeftijd en de Oorzaken Dood.

available are the same for all the armies. The Netherlands records the number of soldiers treated, France, Germany and Italy the number of admissions to infirmaries and to hospitals, Belgium and Spain admissions to hospitals and the other countries, except Czechoslovakia, simply admissions. Czechoslovakia reports for 1921 to 1924 admissions to hospitals and other

soldiers in India. The three higher average rates are 99 for the United States Army (all stations), 149 for the Japanese Army, and 46 for soldiers from the British Isles in India.

The Japanese average rate is based upon only five years, and two of these years (1914 and 1915) were during the World War. The rates in these years were about five times as

cases lasting twenty or more days and ensuing death or discharge but, after 1925, all cases lasting three days or more or causing death or discharge. Even without quantitative allowances (which seem impossible) for these differences, the figures give useful information.

Comparisons. The average rates for most of the armies listed range from .024 for Spain to .43 for Belgium. (The figure for Belgium includes an unusually high rate in 1906.) It is noteworthy that within these limits are included also the averages for French soldiers in Morocco and in Algeria as well as that for native

high as in the other years and, therefore the average rate given for Japan is probably higher than the normal.

The average rate of .99 for the American Army in the United States is for the years 1920-1924 and 1927-1931. It includes cases not only among White but also in Colored soldiers. For the period 1927-1931 we have figures for each camp or station in the United States and for stations elsewhere as well. Rates based upon these figures vary in the United States from .19 to .3. Rates of 1.3 were shown both for the northern and for the southern central States lying

east of the Mississippi River but the highest rate was for the southern States on the Atlantic Coast. The lowest rate was for the Pacific Coast and that for the Rocky Mountain States was nearly as low. The rate for White soldiers in Panama Canal Zone was 1.3 and the rates for the Philippine Islands and for Hawaii were very low. The average rate for stations in the United States for the period (1927-1931) was .94 while that for the tropical stations mentioned above was 5.7. The rate for white soldiers in the Philippine Islands was 6. Thus, the comparative frequency of heat effects in the United States is again brought out.

As a rule, the annual fluctuations of rates for most of the armies are not great but there are noteworthy exceptions which are italicized in table 2. Extreme fluctuations are shown for soldiers from the British Isles stationed in India in 1918 and in 1921.

Deaths The procedure in reporting deaths from heat in the various armies differs considerably. The number of deaths recorded is insufficient for useful statistical comparison.

HEAT EFFECTS IN CERTAIN NAVIES IN RELATION TO STATION

Data The average morbidity rates for the British Navy and for the French Navy, when compared with those for specific "stations", show very striking differences (table 3). In

TABLE 3

BRITISH NAVY

Average Morbidity Rates, 1921-1930, by Stations

Stations	Rates per 1,000	
Home	0.14±	0.05
Atlantic Fleet	0.13±	0.06
Mediterranean Station	.90±	.11
America and West Indies	1.2 ±	.42
China	4.38±	.51
East Indies	13.5 ±	2.1
Africa	1.33±	.56
Irregular List	5.50±	.9
Total Force Average	1.09±	.06

FRENCH NAVY

Average Morbidity Rates, by Stations
1902, 1904, 1906 to 1911

Stations	Rates per 1,000	
Méditerranée	0.4	
Atlantique	0.2	
Extrême-Orient	1.0	
Océan Indien	4.2	
Pacifique	1.8	
Indo-Chine	0.7	
Station Locale du Sénégal	1.8	
Forces Navales, Maroc	0.7	
Total Force Average	1.8	

the British Navy the rate for the "East Indies Stations" is extremely high and that for "China

Stations" is notably high. The rate for the French Navy in the Indian Ocean is also notably high, but that for Indo-China is not high.

COMMENTS ON SECTION II

The data provided in this section amplify to some extent the information as to the distribution and prevalence of heat effects provided in Section I.

The following important facts are shown in table 2:

1 The rates for the American Army in the United States are markedly high.

2 The rates for soldiers from the British Isles in India are extraordinarily high whereas those for native soldiers are comparatively low.

3 The rates for French soldiers in Morocco and in Algeria and those for native British soldiers in India are nearly equal.

4 The data for the British and the French Navies in the Far East seem somewhat discordant.

SECTION III

DATA FROM VARIOUS PARTS OF AFRICA

General Observations Some hospital statistics of heat cases in various parts of Africa have been summarized in table 4. The figures are for cases treated in hospitals or dispensaries, that is to say, for "in-patients" and "out-patients". The deaths are given for in-patients only. In some instances the cases are recorded for Europeans and for natives separately but in other instances these groups are not separated.

The validity of admission rates depends upon the degree of accuracy of the figures for population as well as on the completeness of the reporting of cases. The figures for the European population and its cases are, doubtless, much nearer the truth than those for the native populations. The European population is more accurately known and Europeans are more likely to apply for treatment. On the other hand, native populations can seldom be determined accurately and, in general, the natives are so widely distributed that comparatively few of them are within reach of a hospital when acutely ill. Rates for native population should, therefore, be based upon the number of those to whom treatment is available in fact.

Official data from the Belgian Congo take this aspect of the problem into account. The Belgian tabulations are headed "Mouvement Général de la Morbidité et de la Mortalité dans les Rayons d'Actions des Médecins". The report for the Belgian Congo in 1925 records 3,399 deaths from all causes among the Blacks and a death rate of 14.2 per M. The population within the sphere of action of the physicians must, therefore, have been considered to be 240,000. But, inasmuch

as the total population of the Belgian Congo is about 8,000,000 it appears that morbidity and mortality were recorded for only about one thirtieth of the population.

Rates for Europeans have not been determined when less than ten cases were recorded.

Regional data are presented in tables 5, 6, 7 and 8 for the Belgian Congo, Nigeria, the Anglo-Egyptian Sudan and the Union of South

in Katanga than in the other Provinces of the Belgian Congo.

In Nigeria (table 6), the great preponderance of cases among Europeans is again shown. There was a marked variation from year to year in the number of Europeans treated.

The outstanding fact for the Anglo-Egyptian Sudan (table 7) is that 104 natives in the year 1932 were admitted to hospitals for heat effects.

TABLE 4

CASES OF HEAT EFFECTS IN VARIOUS PARTS OF AFRICA AS SHOWN BY HOSPITAL STATISTICS

Africa respectively. Inasmuch as few Europeans are treated for heat effects in any year, the fluctuations in their numbers may not be significant.

When the relative proportion of Europeans to Natives (see table 4) is taken into account, table 5 emphasizes the much smaller proportion

whereas, in other years, the numbers admitted were small. Moreover the number of European cases treated in 1932 was not unusual. It seems probable that the large number of heat cases among natives in 1932 was not due to unusual heat but rather to some unusual employment involving unnatural conditions of life.

TABLE 5

Census 1918—males 727M, females 691M
1926— " 857M, " 820M

Death rates 0.7 per 100,000 males, 0.2 per 100,000 females

Death ratio of males to females = 3.6

Africa are not directly comparable with those from other parts of the world

2 The death rates in the Union of South Africa, from heat, based upon the white population (table 8) are considerably lower than those for the United States of America (table 1). The ratio of males to females is 3.6. Thus the preponderance of deaths of males to females there is even greater than in the United States of America where the ratio over a period of thirty-one years was 2.5.

3 Admission rates for heat effects among Whites, as shown by hospital statistics, is very high in Nigeria, notably high in Nyasaland, and strikingly lower in the Belgian Congo (table 4). No comparable rate can be figured for the Anglo-Egyptian Sudan because the number of Whites living there is not known to us.

4 Deaths from heat are not numerous even among Europeans in the parts of Africa referred to, but it is evident that the Europeans are far more susceptible to heat than are the Native races.

SECTION IV

HEALTH REPORTS FROM FRENCH DEPENDENCIES IN AFRICA AND IN ASIA

Through the good offices of Dr F. Sorel, Médecin Général Inspecteur des Troupes Coloniales, Ministère des Colonies, one of us (G. C. S.) was permitted to examine a large number of typewritten reports in the files of the Ministry of the Colonies. These reports were from officials of the Civil Government having administrative duties, from officials of the Medical and Sanitary Service or from Government Hospitals and Dispensaries. Included among them was a single Military Report from French Somali land.

AFRICA 1933

Circonscription de Dakar The number of inhabitants was stated to be approximately 70,000 of whom 45,000 lived in the city of Dakar and 25,000 in 14 villages.

Racial classification

Europeans	5,312
Syrians or Moroccans	1,877
French half-breeds and foreigners	2,367
Native races	58,548

There were forty-one deaths during the year among the Europeans. These deaths were classified under thirty-two heads but no death from heat effects was mentioned. Among assimilated races there were twenty-one deaths listed under nineteen heads but heat effects were not mentioned. Neither was heat mentioned as a cause of death among the natives.

Senegal The *Hopital Colonial de Saint Louis* treated during the year 445 cases in Europeans or in persons belonging to assimilated races. Of these six died. The number of natives treated in the hospital was 1,306 and many more were treated in dispensaries. Heat is not mentioned

Colony of Mauritania. A report on aid to the native population puts their at about 240,000. The report says that where so much as in Mauritania has created such distinct morphologies which react diversely to morbid conditions report discusses infectious and parasitic cases, and says that attendance at the series is large and is increasing. Not said of heat effects.

French Soudan The *Hopital du F* (five kilometers from Bamako) treated Europeans and 110 natives in 1932. A European and ninety-five natives in 1933. A single case of insolation occurred in a peasant.

Niger Colony A report states that generally, the climate is excellent for Europeans but that the natives are not much disturbed. Mention is made however of a tendency of mental equilibrium by Europeans as the seasons change. Among fifty-two patients hospitalized at Niamey, no cases were attributed to heat, and heat is not mentioned as having either morbidity or mortality among Europeans or natives.

Ivory Coast During the year forty-six of Europeans and 1,507 deaths of natives reported by physicians. Heat is not mentioned as a cause of any of the deaths.

Dahomey Heat is not mentioned as a cause of morbidity or mortality among cases in the medical services.

French Guinea. Heat effects are not mentioned among the important diseases of the year.

Gabon and other Colonies. If any ill effects of heat were observed by members of the Service these cases were so few as to have been included under the head of "maladies diverses." Reports of health conditions from the Ministry of the Middle Congo, from the region of Chad and from the Oubangi-Chari Territory do not mention heat effects.

French Somaliland Cases of illness mentioned at the *Hopital Colonial de Djibouti* during the year came not only from the Colony but from ships. No case of illness due to heat was mentioned in the report of this hospital.

A report of the *Service Médical du Port de Miltane*, however, says that although the season is very uncomfortable the climate is healthful and well borne by Europeans that "coup de chaleur" seldom attacks a prudent or plethoric individual most often alcoholics. During the year one European died from heat.

ASIA 1933

Annam The numbers of cases treated in hospitals or dispensaries during the year were

	European	Native
Males	470	21,122
Females	250	18,832
Children	122	5,635

Three cases of "coup de chaleur" were recorded. All three patients were men. Two were Europeans and the third a native. All three recovered.

Cochin China The number of patients treated in hospitals and clinics during the year was as follows:

	European	Native
Males	600	29,409
Females	576	41,623
Children	267	7,229

"Coup de chaleur" occurred in four male natives but was not observed in any of the Europeans.

Tongking Many thousands of patients were treated in government hospitals or dispensaries. The morbidity was relatively high from April to October and especially in May. More than 70,000 natives were treated (males 27,501, females 34,633, children 9,049).

Seven heat cases were observed as follows: four men, two women, one child (whites or natives or both?).

Protectorate of Cambodia hospital cases:

	European	Native
Males	183	6,459
Females	129	3,335
Children	57	562

Cases of "coup de chaleur": two males, one a European and one a native. Both patients recovered.

Laos No heat cases were reported. Hospital cases were as follows:

	European	Native
Males	50	3,742
Females	15	2,253
Children	4	835

COMMENTS ON SECTION IV

It is evident that ill-effects of heat in the French Dependencies in Africa in the year 1933 were so few as not to constitute a serious problem. Only two such cases with one death were mentioned in the reports examined. Both cases were in Europeans. One case occurred in the French Soudan and the fatal case in French Somaliland.

An official in Paris said that heat cases were common twenty years ago in the French Colonies and that the sun is still feared there but that all persons wear the "casque" today and that, by virtue of the precautions dictated by experience, heat cases have become scarce.

Small numbers of heat cases were reported in 1933 from the French Colonies in Asia. Their numbers were insignificant, however, as com-

pared with the large numbers of patients treated, and still more so with regard to population.

SUMMARY

All available data having been collected, we have attempted to ascertain the distribution of heat effects and their comparative frequency in different parts of the world. The data obtained are very inadequate for the purpose. It is believed, however, that they justify the following conclusions:

1 The death rates attributed to heat among European residents of Shanghai and among the population of the Republic of Panama are outstandingly high.

2 Heat effects are notably common in the United States and in Australia.

3 Soldiers from the British Isles stationed in India frequently suffer from heat effects.

4 The frequency of heat effects appears to differ markedly in various parts of tropical Africa. Cases appear to be decidedly more numerous in some of the British Colonies (Nigeria, Anglo-Egyptian Sudan, Nyasaland) than they are today in French or in Belgian territory.

5 In the Tropics in general, persons of European race are attacked far more often than are persons of the native races, but the latter are by no means immune (Anglo-Egyptian Sudan).

6 Males are far more liable to heat effects than are females.

7 Heat effects are comparatively uncommon in the West Indies, in the British Isles, in Europe, in the Union of South Africa and in Japan.

8 Notably low rates are exhibited for Finland, Sweden, Ceylon, New Zealand and Lima (Peru). Deaths from heat are recorded as nil in Mauritius in the Indian Ocean.

9 There are outstanding fluctuations in heat effects in several countries in certain years. To explain these, it may be necessary to localize the cases sharply, to determine the climatic conditions from day to day in the places where the heat effects were most numerous, and to learn whether there had been marked coincident changes in occupation or mode of life among the victims.

10 It has been said that heat cases were common in the French Dependencies twenty years ago but that they have been few in recent years. Reports for the year 1933 from French Dependencies in Africa and in the Far East indicate a striking scarcity of heat cases.

11 The irregular world distribution of acute effects of heat which the data indicate may be, to some extent, fallacious. Incomplete reporting, different methods of recording or of classification, or incorrect figures for population

might cause misleading irregularities in the figures

12. Some real irregularities of distribution can, probably, be explained as due to climatic factors which are peculiar to restricted localities

13. It is interesting to note that acute effects of heat are common in some parts of the tropics and not in others, and that the same is true of the temperate zones. These facts indicate the need of further study to explain the distribution of heat cases with reference to probable causes, climatic or other. Work on this problem will be undertaken in the near future

ANESTHETIC EMERGENCIES*

BY URBAN H. EVERSOLE, M.D.†

THERE is no rule by which situations arising during the course of anesthesia can be divided into emergencies and nonemergencies. Many situations may arise that do not within themselves appear to constitute emergencies but if the anesthetist is not prepared to cope with them they may easily develop into real emergencies.

PREVENTION OF EMERGENCIES

Undoubtedly the most satisfactory method of dealing with an emergency is its anticipation with the consequent taking of steps for its prevention. An emergency may often be anticipated from a consideration of the condition of the patient or the type of operation.

THE PATIENT

1 Obviously patients who are poor risks either from debility, age, or long-standing infections such as tuberculosis, as well as those suffering from severe cardiac lesions, are more likely to give difficulty during the course of an anesthesia.

2 Serious obstruction is to be anticipated in patients who have lesions of the neck or throat causing tracheal compression or deviation. When this condition is suspected x-rays should be taken previous to the anesthesia to determine the degree of tracheal abnormality. Adenomatous goiters of the intrathoracic type constitute a large portion of the above group.

3 Patients with intrathoracic exudative lesions such as lung abscess, active tuberculosis, and bronchiectasis often have a great deal of difficulty due to the exudate, which may be aspirated into the good lung and thus result in spreading of the infection or the actual drowning of the patient. If this type of patient is operated upon, intratracheal anesthesia should be used and adequate facilities for aspiration of the air passages should be available at all times.

4 Chronic alcoholics constitute a group which may give the anesthetist a great deal of difficulty because of their great resistance to

anesthetic agents, particularly ether. They require heavy preoperative medication and are poor subjects for inhalation anesthesia. When the condition of the patient and the type of operation warrant its use, spinal anesthesia is preferable in these cases.

THE OPERATION

1 Operations on the neck where there are manipulations around the trachea often cause serious obstruction from a reflex spasm of the vocal cords. This is caused by stimulation of the surface of the trachea or of the laryngeal nerves. Treatment of this condition is discussed later under Mechanical Obstructions of Respiration.

2 Severe drop in blood pressure is to be anticipated when, during the course of an operation, a marked shifting of the position of the patient is necessary, as in the change to the Sims' (or even worse, the prone position) from the dorsal recumbent position in an abdominal perineal resection of the rectum. The administration of 2 to 4 cc of a 1 to 1000 solution of adrenalin intramuscularly five minutes before the change in position often is of value in preventing such a radical drop.

3 In a thoracic operation respiration is greatly hampered due to the position of the patient on the table. The good lung is on the dependent side and the chest wall often splinted by braces, thus greatly limiting chest expansion and making it very difficult to maintain surgical anesthesia and adequate oxygenation with such weak anesthetic agents as nitrous oxide or ethylene. This difficulty is overcome by the use of cyclopropane¹.

Respiration becomes a greater problem in these operations if the pleural cavity is open. However, when one pleural cavity only is open spontaneous respiration usually continues uninterrupted, particularly if the opening is large. A small opening may cause more air to be drawn in than is expelled with a consequent compression and mediastinal shift. Of course the accidental opening of both pleural cavities necessitates immediate artificial respiration, which can very easily be carried out by means of rhythmic manual pressure on a rubber breathing bag if a closed type of inhalation anesthesia

*From the Department of Anesthesia, the Lahey Clinic, Boston, Mass.

is being used. Pressure equivalent to seven to eight millimeters of mercury is usually sufficient to prevent collapse of the lung while 22 mm should not be exceeded. With a mobile mediastinum sudden opening of a pleural cavity may cause a patient to go into collapse due to flapping of the mediastinum. We feel that all intrapleural operations should have intratracheal anesthesia.

MANAGEMENT OF EMERGENCIES

General Classification of Anesthetic Emergencies

- 1 Respiratory
- 2 Circulatory
- 3 Miscellaneous

I. Respiratory Difficulties

- (a) Mechanical obstruction of respiration
- (b) Disturbances of the respiratory center
- (c) Miscellaneous respiratory difficulties

(A) MECHANICAL OBSTRUCTIONS

Any type of respiratory obstruction however slight, may become a serious complication during the course of anesthesia and an immediate attempt should be made to rectify it.

(1) One of the most common causes of respiratory obstruction is laryngeal spasm, a condition in which the vocal cords are in adduction, either partially or completely obliterating the air passage. This can be caused by irritation due to the anesthetic agent, reflexly by stimulation of the trachea or laryngeal nerves, or during an abdominal operation under light anesthesia by stimulation of the splenic nerves or traction on the mesentery.

In most instances the administration under slight pressure (about 10 mm of mercury) of high concentration of oxygen with a small amount of carbon dioxide is sufficient to relieve the spasm. If the spasm is due to tracheal or laryngeal nerve stimulation it may be necessary to stop the operation for a short time so that the obstruction can be cleared. Occasionally it may be necessary to force an intratracheal catheter between the cords to relieve the obstruction and in rare cases a tracheotomy may be necessary.

(2) Obstruction to respiration may be due to outside pressure on the trachea from a neck tumor such as an intrathoracic goiter causing deviation and compression of the trachea. Any case in which there is actual compression of the trachea (and this can be determined previously by x-ray) should have an intratracheal catheter in place before the operation begins. We have found the flexible metal catheter designed by Flagg and later modified by Woodbridge² of this Clinic, to be very satisfactory because of its extreme flexibility and resistance to compression.

(3) Common types of obstruction, usually of

minor consequence (though they may become serious), are those due to the dropping back of the tongue under anesthesia, tight compression of the lips, or flutter of the relaxed soft palate or alar nasi. These can usually be relieved by the use of either nasal or oral breathing tubes or by forcibly extending the chin.

(B) DISTURBANCES OF THE RESPIRATORY CENTER

(1) Pathological from increased intracranial pressure

(2) Drug depression divided as follows

(a) Too heavy preoperative medication with a depressant drug such as the opiates and the barbiturates causes respiratory depression. The depression may be sufficiently great to result in cessation of respiration before anesthesia of sufficient depth is reached. This is particularly true when a respiratory depressant anesthetic such as cyclopropane is being used. This difficulty can usually be overcome by the administration of small amounts (200 to 300 cc per minute) of CO₂ for a short time. For cases in which cyclopropane is to be used we reduce the preoperative medication, our average dose being morphine sulphate grains 1/8 and scopolamine hydrobromide grains 1/150 given subcutaneously one hour before operation whereas with ethylene or nitrous oxide we usually give 1/6 grain of morphine and 1/150 grain of scopolamine and in addition three grains of nebutal by mouth one and one half hours before operation. These doses vary according to age, weight and general condition of the patient.

(b) Paralysis of the respiratory center with cessation of respiration of course occurs when an inhalation anesthesia is carried to too great a depth (4th stage of anesthesia). If this inadvertently occurs, administration of the anesthetic agent should immediately be stopped and oxygen with CO₂ administered by means of artificial respiration.

(c) Avertin anesthesia is frequently accompanied by a marked degree of respiratory depression which may persist for several hours following the operation. The period of post-anesthetic depression may be materially shortened by the administration of 1 to 5 cc of coramine intravenously. We have found this drug to be of greater value than the more commonly used respiratory stimulant, caffeine sodium benzoate.

the alcohol is injected slightly below the level of emergence of the involved roots. In view of the pathological findings in case 13, it seems

FIG 3 Note the difference between the level of emergence of the nerve roots from the cord and the level of the corresponding vertebral interspace (after Ranson)

likely that paralysis of the sensory fibers in the cauda equina may account for successful results when the injection is made below the supposedly optimum site. A number nineteen

FIG 4 The segmental innervation of the body

gauge needle was used and in our later experience an amount of spinal fluid equivalent to the amount of alcohol to be injected was withdrawn. The head of the patient was kept at a lower level than the site of injection and the spine was flexed to as acute an angle as possible at this point (see fig 1). Eight-tenths to two cubic centimeters of the alcohol mixture was slowly injected, taking at least one full minute for each cubic centimeter. In cases in which sacral nerve segments have been involved we have kept the entire lower lumbar and sacral segments elevated above the site of injection. This procedure is carried out on an operating table, which greatly facilitates adjusting the position of the patient. Occasionally it may be more convenient to make the injection with the patient in bed. Following the injection the patient is kept as nearly as possible in the same position for four hours. Afterwards he should be kept flat in bed for twelve hours and confined to bed for several days. Attempts to get patients up sooner have caused distressing headaches. We have found the preoperative administration of phenobarbital, 200 milligrams, and morphine, 10 to 15 milligrams, advantageous in keeping patients comfortable during the period following the injection at which time there usually occurs an uncomfortable burning sensation which is always transient.

The dosage must be determined by the conditions existing in each individual case. The larger amounts of one and one-half to two cubic centimeters allow the alcohol to affect a wider area at one injection. In our experience no serious complications have followed the use of the mixture of ethyl and methyl alcohol in doses up to two cubic centimeters. On the other hand, in one case in which two cubic centimeters of absolute ethyl alcohol was used, acute retention of urine developed and persisted until death. It is far better to err on the side of conservatism as reinjection can be performed easily, and serious complications may follow large doses. The maximum dose, therefore, should not exceed two cubic centimeters of the mixture of ethyl and methyl, or one cubic centimeter of ethyl alcohol.

RESULTS

Yeomans⁶, Saltzstein⁷, and Stein² have reported satisfactory results from the subarachnoid injection of alcohol. During the last two years it has been employed in a selected group of cases on the urological and surgical services of the Peter Bent Brigham Hospital. Although the number of cases is small it seems worth while to report the results, as the collective experience of different investigators leads to the more rapid acceptance or rejection of such a technically simple but potentially dangerous procedure.

Table 1 is a summary of our results to date

In six cases the result was very satisfactory, in five cases there was either definite improvement without complete relief, or marked improvement, but with rapid recurrence of the pain. Two cases were accounted as failures. The satisfactory results were obtained in cases of carcinoma of the cervix, bladder, testicle and prostate. Improvement without complete relief occurred in the same type of cases*. In general, the more extensive the lesion the less satisfactory was the result. This can be seen from table 1 and figure 5, which show that the more nearly the anesthetized area coincided with the painful area as mapped out on the skin the more successful was the result. Bilateral cases were particularly disappointing. In the cases (1, 4, 12) in which the pain was referred to a peripheral somatic nerve (sciatic) dramatic relief was obtained. When the pain was more deep-seated and less sharply localized often being heavy and boring in character the results were much less satisfactory. It is our impression that so-called visceral pain is less amenable to this form of therapy than is somatic pain, probably due to the fact that as Davis* has emphasized, the abolition of visceral pain requires the section or blocking of a large number of posterior roots.

However, even in the cases in which we have not obtained an entirely satisfactory result the measure of relief obtained has been so appreciated by patients and relatives that we felt the injection was worth while. Of the two cases that are accounted as failures, one was a patient with cancer of the bladder who had a large sacral cyst which may have communicated with the subarachnoid space. At any rate three injections by two different surgeons produced no anesthesia. The other case was that of a neurotic woman who complained of pain in the distribution of the ilioinguinal nerve following nephrectomy. Although definite anesthesia was obtained over the course of the nerve the patient continued to complain of pain. In retrospect we feel that the selection of this case was ill advised not only because of the neurotic nature of the patient, but because of the benign character of the lesion.

In successful cases the relief of pain is extraordinary. In our cases the pain disappeared dramatically within a few minutes or an hour after the injection, although in one case it was delayed for almost a week. Dogliotti and Stern have noticed this occasional delayed effect also but in our case (case 11) it may have been due to roentgen ray therapy rather than to the delayed effect of the alcohol. Our observations confirm those of Dogliotti in regard to the character of the anesthesia. It is as if nerve filaments rather than an entire nerve were blocked. Thus in

our most successful case in which dramatic relief of pain was obtained for nine months, the patient was able to appreciate a stout pinprick in certain portions of the anesthetic area, light touch was not entirely abolished, and temperature sensation was hardly affected. Yet the threshold of pain was raised sufficiently to provide complete relief. In other cases, particularly those in which large doses were used, pain, temperature, and tactile sensation have been completely abolished and reflex activity greatly diminished.

COMPLICATIONS

Although the subarachnoid injection of alcohol is still in point of fact a clinical experiment without complete laboratory investigation to guide it, serious complications have not been common. Theoretically a respiratory paralysis may occur from a rapid diffusion of the drug upwards in the cord. It has not been reported and we have had no difficulty in this respect. If care is exercised in keeping the patient's head lower than the site of injection this complication should be impossible. Motor paralysis and loss of sphincter control of the bladder and rectum may occur. Permanent motor paralysis has not occurred although transitory weakness is common. It was seen in seven of our thirteen cases. Sphincter paralysis occurred in one case in which two cubic centimeters of absolute ethyl alcohol were used. It was characterized by acute retention of urine persisting until death ten days later. Stern* feels that paralysis of the sphincters can be avoided if doses of not more than eight-tenths of a cubic centimeter are used for injections low in the cord. This applies to absolute ethyl alcohol, but we feel it is safe to use the mixture of ethyl and methyl alcohol in doses up to one and one half cubic centimeters at low levels. Meningismus occurred in two cases persisting for several days after the injection. Examination of the spinal fluid five days after the injection in one of these cases showed a slight increase in total protein and lymphocyte count.

FAILURES AND REINJECTIONS

Injections have been repeated in four of our cases excluding the two in which bilateral injection was done. As has already been emphasized, in practically all cases in which relief of pain was not obtained the anesthetic area did not coincide with the painful area (fig 5). We attribute this partly to our inability to control accurately the localization of the injected alcohol but also, to an inevitable defect in the method, for, in order to block an extensive group of nerves it is necessary to use amounts of alcohol in excess of the margin of safety. For this reason we prefer the mixture of ethyl and

*We have had no experience with lesion in dividing area above the level of the twelfth dorsal nerve but injection may be made high as the first thoracic nerve.

methyl alcohol, because in our experience it permits the use of amounts up to two cubic centimeters without complications. No matter how careful the technic, there will be cases in which reinjection is imperative even in unilateral involvement.

less the condition of the patient the more radical one can be in regard to dosage. The obscurity of the localization of the action of the injected alcohol, and the potential danger involved, preclude its use in benign conditions. For patients having incurable carcinoma the

FIG 5 In successful cases the anesthetic areas and painful areas as mapped out on the skin have coincided

It is evident that while the subarachnoid injection of alcohol for the relief of intractable pain is very useful, it has not always been satisfactory. Moreover, the margin of safety between sensory relief and motor damage is small. Consequently, we feel that for the present at least, this procedure should be reserved for patients with incurable disease. The more hope-

procedure can be recommended without reservation.

SUMMARY

1 Results are reported of observations on thirteen subarachnoid injections of alcohol for the relief of pain.

2 Excellent results were obtained in six

cases, incomplete relief in five cases, failure in two cases.

3 In those cases in which complete relief was not obtained the nerves to the painful area were not adequately blocked, as the anesthetic areas and painful areas did not coincide. Visceral pain is less amenable to this form of therapy than is somatic pain.

4 The method is recommended for the relief of intractable pain in patients with advanced cancer.

PRIMARY CARCINOMA OF THE JEJUNUM WITH REPORT OF TWO CASES

BY E. M. HODGKINS, M.D.*

PPRIMARY adenocarcinoma of the small intestine, whatever the location, is so rare in the individual experience that most authors on the subject consider it a pathological curiosity. Recent reports emphasize the fact that this is especially true of the proximal jejunum. A review of the literature on the general subject of small intestinal malignancy immediately impresses one with the absence of a satisfactory working hypothesis for dealing with the lesion. This fact is not surprising when one considers the small number of cases thus far reported. Evidently no single surgeon or group of surgeons has encountered all of the varied difficulties in diagnosis and treatment that may arise from the many forms of this disease and therefore definite conclusions are not justified. Collective grouping of the cases has been most unproving. In spite of this, the effort toward a better understanding of the subject goes on within a group of large clinics which will eventually dispel present confusion.

From a diagnostic viewpoint sex and age incidence, early and late symptom syndrome, roentgenologic characteristics, predilection for location, cell morphology, period of metastatic activity in different types, all of which are so important in other cancer locations, fail to find agreement here. The following brief statistical abstracts from the literature are interesting, and will serve to emphasize the rarity of the disease and certain striking disagreements.

The necropsy tables afford the best statistical account of small intestinal cancer and the reports of Notinagel and Geiser are impressive. The former found only ten cancers of the small intestine in a total of 3585 cancers in 41,838 necropsies, Geiser but two in a total of 909 cancers in 11,314 necropsies.

Muller in 5621 necropsies, found cancer of

the jejunum and ileum in only three cases. Proportional number in each not stated.

Forgue and Chavin in a series of 85,031 necropsies found carcinoma of the small intestine in only 04 per cent of the total examinations.

Bunting reported one case of carcinoma of the small intestine in 2,200 necropsies.

McKenty reported two cases occurring in the small intestine in 2,500 necropsies.

Johnson, at the Vienna General Hospital, in 41,838 necropsies, found 343 intestinal cancers, ten of which were in the ileum and none in the jejunum.

Clinical reports show great variance in incidence. For example, In 1919 Judd reported twenty-four personal cases of primary cancer of the small intestine, eleven of which were located in the jejunum.

Craig, in 1924, studying the regional lymph glands in thirty-six cases of small intestinal cancer found only four cases of primary carcinoma of the jejunum.

Vickers in 1924 stated that for any given unit of length of small gut, the jejunum shows the greatest relative immunity to cancer. Allbutt and Rolleston have noted that in their experience primary carcinoma of the jejunum is very rare.

Morrison in 1927 writing on primary carcinoma of the proximal jejunum stated that the lesion is very uncommon and is usually discovered at autopsy or when the abdomen is opened for other causes.

Bongolea and Buzterrica in 1930 writing on cancer of the small intestine stated that the most frequent location of primary cancer is the terminal ileum and except for the duodenojejunal junction primary carcinoma of the jejunum does not exist. This is a most contradictory opinion.

Newton and Buckley in 1930 emphasized the rarity of this lesion by summing up the re-

Hodgkins, E. M.—Assistant Professor of Surgery Tufts College Medical School. For record and address of author see "This Week's Issue," page 491.

ported statistics of European clinics and adding personal reports from eight of the largest hospitals in this country. The result was thirty-five histologically verified cases among 135,000 necropsies.

Bland-Sutton, in 1914, was of the opinion that carcinoma in the duodenum occurred more commonly than in either the jejunum or ileum.

Rankin and Mayo in 1930, writing on carcinoma of the small bowel, stated that in the Mayo Clinic up to that time, there had been only fifty-five cases of carcinoma of the small intestine as against 4,597 of the large bowel including the rectum. In twenty-one cases (38 per cent) the carcinomata were found in the jejunum. They also found that a surprising number of these were at, or a short distance from, the ligament of Treitz. These authors excluded cases of small intestinal carcinoma found in combination with carcinoma elsewhere.

CLINICAL PATHOLOGY

Briefly, there are two general types of carcinoma of the small intestine, i.e., the adenocarcinomas and the carcinoids. The former, although in themselves rare, are well understood pathologically and comprise the larger group of epithelial tumors occurring in this location. The clinical gross appearance is that of an annular constricting tumor partially or completely obstructing the lumen of the bowel, not greatly dissimilar from that of the large bowel tumor. Metastasis takes place early to the adjacent lymph nodes of the mesentery. While infrequent, adenocarcinoma does occur anywhere throughout the entire length of the small intestine. Nevertheless it seems to have a predilection for the first portion of the jejunum near the ligament of Treitz (eighteen to twenty inches distal). From this segment downward, the rest of the jejunum and of the ileum are curiously spared. The terminal ileum is rarely involved at or near its union with the cecum (ileo-cecal valve) but involvement several inches above is relatively frequent. Judd states that in his cases of carcinoma of the ileum, nearly all the growths were several inches above the valve. Most surgeons and pathologists who have had the opportunity of examining malignancy at or directly involving the valve find evidence to indicate that the source of origin is on the large bowel side, and extension by continuity involves the terminal ileum.

In a study of fifty-seven cases Soper found that adenocarcinoma showed a predilection for that part of the small intestine nearest the stomach and colon respectively and an analysis of cases reported by others seems to lend support to Soper's findings.

In accord with this viewpoint, Johnson suggests that the fluid nature of the contents, the

alkalinity of the intestinal fluid and the absence of abrupt bends in the small intestine may be the important factors in explaining this infrequency of growths. There are, however, those that believe that the lesions in the jejunum exclusively are either all metastatic from parent tumors elsewhere or possibly islands of aberrant tissue which have undergone malignant change. Secondary malignant degeneration of aberrant tissue is a proved pathological entity for other locations in the body and therefore is logical here at least in theory if not in fact.

Seidelin and Hernandez have both reported cases of aberrant pancreas in the jejunum which had undergone malignant degeneration and believe that this should always be considered among the causes of carcinoma at this location. Ransom, Oberndorfer, Verse, and Schopper have described what they prefer to call carcinoid tumors of the small intestine as distinguished from adenocarcinoma.

The pathology of carcinoid tumors at present is not well understood so that their ultimate development must still remain in doubt. A large number probably atrophy and disappear entirely. Some may remain stationary and never produce symptoms while a small group will undergo malignant degeneration.

They are variously described as originating from embryonic rests, from the cells of Lieberkuhn's crypts, from aberrant pancreatic tissue, or from basal cell elements in the submucosa. It is, however, now realized that an indeterminate percentage will show pancreatic tissue.

In contradistinction to adenocarcinoma, carcinoids that go on to proliferation are said to extend by local invasion, growing to large size very slowly, often obstructing without metastasizing at all or starting metastasis very late. The consensus is that they are practically confined to the jejunum.

SUGGESTED TREATMENT

From analyzing a large number of reports on the subject of carcinoma of the small intestine a practical working hypothesis is suggested. Disregarding the duodenum it may be assumed that the preponderance of malignant epithelial tumors occur at the *near* proximal jejunum and the *near* terminal ileum. Thus, the exploring surgeon, in searching for suspected malignancy in the small intestine is able immediately to eliminate these areas and by so doing save valuable time and handling of the bowel. In general, the treatment of large malignant bowel tumors is complete removal of the area involved with its adjacent mesentery. In the instance of small carcinoid tumors discovered early, wide removal locally without resection of the adjacent mesentery should be sufficient to effect a cure. Large carcinoids either partially or com-

pletely obstructing the bowel should be treated as potential adenocarcinomas. End-to-end or end-to-side anastomosis reestablishes the continuity of the bowel after resection.

In the presence of metastasis or because of the attendant obstruction when one does not feel justified in resecting the bowel, a palliative entero-anastomosis may be used to sidetrack the pathological lesion thereby relieving the obstruction and prolonging life.

In support of the theory that aberrant pancreatic tissue produces carcoid tumors in the jejunum and does undergo malignant degeneration, the following illustrative case is submitted. In addition, a case of primary adenocarcinoma of the jejunum in which early operation resulted in cure is reported.

CASE REPORTS

CASE 1 Mr. L. J. White, aged sixty-four years, was seen in consultation with Dr. A. N. Allen, June 2, 1927. The patient gave a history of periodic attacks of indigestion over a period of twenty years. All food eaten produced distress in the region of the epigastrium. "Heartburn" came on immediately after eating followed by a feeling of nausea. He vomited only occasionally and there was no blood in the vomitus at any time. The vomitus contained sour tasting undigested food. The patient never noticed any tarry appearance of the stools.

In 1926 he had a severe attack of pain in the abdomen with continuous vomiting of everything ingested. Under his physician's care he was given medicine and placed on a liquid diet. Recovery was prompt. Roentgenological examination was suggested to him but this was deferred inasmuch as he felt so much better. He continued on a restricted diet with reduction of symptoms. More recently symptoms have been getting worse with inability to take even liquids without pain and fullness in the epigastrium and frequent vomiting. Nausea is now present when the stomach is empty which has never been experienced previously. There is still no blood in the vomitus. He feels weak and tired constantly.

Physical Examination The patient was fairly well developed, although poorly nourished. His skin was dry and showed no jaundice. The findings of the heart and lungs were within the normal. Reflexes were normal.

The abdomen was scaphoid in appearance, the skin over the abdomen was thin and loose and almost devoid of subcutaneous fat. Weight 107 pounds. Abdominal palpation revealed general mild tenderness throughout with a specific sensitive point with spasm high in the epigastrium just slightly to the right of the midline. There was thought to be a possible mass on deep pressure but this was not certain.

Laboratory Examinations The laboratory examinations showed the white blood count to be 9700. Red blood count 4000000. Urine concentrated although otherwise normal. Stools showed faint blood by guaiac test. A test meal for analysis of the stomach contents was not done.

Roentgenological Examination Barium meal was given. The greater and lesser curvatures of the stomach were well defined. The duodenum filled in completely. Six-hour examination shows a two-thirds stasis of one-half the meal.

Roentgenological Diagnosis Obstruction of the

pylorus possible ulcer. Malignancy is a strong possibility in this case.

Diagnosis Pyloric obstruction malignant.

Operation Under nitrous oxide gas oxygen and ether the abdomen was opened through a high right rectus incision. Exploration showed the gallbladder, pancreas, kidneys and spleen to be normal. Examination of the stomach revealed an almost complete obstruction at the pylorus due to multiple ulcers and wide induration. The duodenum was normal. Resection of the pylorus and ampulla of the stomach was decided upon. The nodule of the stomach was adherent to the pancreas but separation was done without causing injury to this structure or excessive hemorrhage. The cut ends of the stomach and duodenum were closed tightly in the usual manner as a Billroth No. 2 type of anastomosis seemed advisable. On drawing up the proximal loop of jejunum in preparation for posterior gastrojejunostomy a small tumor was discovered on the anterior wall about eleven inches from the ligament of Treitz. This tumor was approximately the size of a five-cent piece, ovoid in shape, hard discrete with excrescences on the surface and yellowish gray in appearance. The appearance was that of an early carcinomatous tissue. This presented a problem as the tumor was located at just the point where anastomosis should be done. Local excision was possible as the jejunum was of good size and the loss of tissue would not interfere with a good anastomosis. Clamps were applied around this area and the tumor removed by means of an elliptical incision. The resulting aperture was anastomosed to the posterior wall of the stomach and made a satisfactory stoma. The patient stood the operation well leaving the operating room with pulse of 114 good volume. Treatment was administered in bed for mild shock.

Pathological Report Specimen of ulcer of jejunum received June 3, 1927.

Microscopic examination shows adenocarcinoma. A considerable amount of pancreatic tissue was present in the muscularis.

Specimen from pylorus received June 3, 1927.

Microscopic examination shows no malignancy. Specimen from gland shows no malignancy.

Outcome This patient has been seen frequently in the past eight years by Dr. Allen and the author. He remains in excellent health and his present weight is 140 pounds.

The following roentgenological examination by Dr. Albert M. Moloney, February 27, 1932, is interesting in that it shows a satisfactorily functioning stomach and jejunum.

Roentgenological Examination by Dr. Albert M. Moloney Checkup films show a smooth bordered, operative defect in the distal part of the stomach resulting from resection of its pyloric end. The stomach appears otherwise negative except for a gastro-enterostomy stoma that allowed media to flow out of it.

By fluoroscopy peristaltic waves were seen to pass symmetrically along the course of the stomach. There was no tenderness or apparent defect or intraluminal abnormality noted at the site of defect. On the dependent part of the greater curvature of the stomach, the gastro-enterostomy stoma was found to be functioning normally and there was no tenderness over it.

Films taken one hour after ingestion of the barium meal showed the media flowing freely through normally appearing loops of jejunum in the upper abdomen.

CASE 2 Mr. J. C., aged fifty-one years, April 4, 1930 (this patient came to the clinic complaining of what he termed "pressure" in the abdomen. Sharp pains and cramp-like sensations came on some-

times about two or three hours after eating accompanied by transient nausea and a feeling of weakness. At the onset, which was about a year previous, he did not consider it serious enough to consult a physician because certain patent medicines seemed to give relief. He was only mildly constipated at the beginning, but now goes two or three days without moving the bowels. He has not noticed blood in the stools. One attack of pain was very severe, accompanied by vomiting. There has been no blood in the vomitus, however. Pain, at this time, had radiated around the umbilicus and there was a feeling of increased pressure in the epigastrium. Other than the above complaints, the patient felt well and continued his carpentry. His appetite was fair, and he did not think that he had lost any weight although he couldn't be sure.

Physical Examination The patient was well developed and nourished for a man of fifty-one years. The head, neck and chest were normal with the exception of some gingivitis of the upper and lower incisors. Heart and lungs were normal. Reflexes were carefully tested and proved to be normal.

The abdomen was moderately fat, undistended, soft and nonspastic. At a point in the mid line just above the umbilicus there was some tenderness on deep pressure, although not remarkable or accompanied by muscle spasm. No mass was felt.

Laboratory Examinations Wassermann was negative. White blood count 9000. Red blood count 3,400,000. Stools negative for blood. Urine negative. Gastric test meal showed total acidity normal, free hydrochloric acid content normal, no blood, Oppler-Boas bacilli or sarcinae.

Roentgenological Examination Gastrointestinal. No organic abnormality was found in the stomach. It is of normal size and shape and in six hours is entirely empty showing good motility. The duodenum fills fairly well, uniformly and reveals no characteristic signs of ulcer.

In twenty-four hours the large bowel was empty. At this time we gave a barium enema which revealed the large bowel to be uniformly filled from the rectum to the cecum. There is no evidence of stenosis or in fact any abnormal changes. There is nothing to suggest an organic lesion.

Films of the gallbladder with the Graham test show it to be normal.

Tentative Diagnosis Intestinal malignancy. Location undetermined.

Operation April 8, 1930. The abdomen was opened through a mid-epigastric incision and exploration was done. Stomach, pylorus, duodenum, gallbladder, pancreas and both kidneys were examined and found to be normal. The incision was enlarged and the appendix drawn up into it. The appendix was normal. In exploring further a tumor mass was palpable in the omentum just to the left of the incision. With wide retraction and closer investigation, the tumor was found to be behind the omentum, rather than in the omentum, and located in the proximal jejunum about fourteen inches from the ligament of Treitz. The tumor was enveloping and constricting the bowel so as to cause partial obstruction. There was a good deal of edema both on the proximal and distal sides of the obstruction with dilatation of peritoneal surface vessels. Mesenteric lymph nodes were not enlarged and it was assumed that metastasis had not begun. Complete resection of the tumor and adjacent mesentery was decided upon as advisable and the operation proceeded without difficulty or untoward event. The bowel was anastomosed end to end. An enterostomy tube was considered unnecessary and therefore the abdomen was closed tightly.

This patient's first five days of convalescence were rather stormy, mild distention being the chief diffi-

culty. After this period, the convalescence was smooth and he was discharged from the hospital on the sixteenth day.

Pathological Report April 9, 1930. Received a specimen of jejunum with mesentery attached, and containing constricting tumor.

The section shows a hard mass completely enveloping the intestinal circumference, partially obstructing the lumen.

Microscopic section shows adenocarcinoma.

Pathological Diagnosis Carcinoma of the jejunum.

Outcome This patient has remained in good health for the past five years. He states that he has been entirely free of former distressing symptoms.

COMMENT

To draw conclusions from the two cases herein reported is manifestly not the purpose of this paper. In Case 1, carcinoma of the proximal jejunum was discovered accidentally while resecting a portion of the stomach for obstructing ulcer. Case 2 was undiagnosed preoperatively on account of insignificant symptoms, negative roentgenologic examination and laboratory findings. Exploratory operation was resorted to on account of the patient's age and chronicity of symptoms, such as continued crampy abdominal pains, constipation, distention, transient nausea and moderate anemia, all of which are suggestive of cancer somewhere in the intestinal tract.

To reiterate despite the rarity of carcinoma of the proximal jejunum and terminal ileum, the exploring surgeon will do well to include both these areas in his points of investigation when operating upon a patient, within the cancer age, for gastrointestinal disease.

CASE 22101

PRESENTATION OF CASE

A twenty nine year old white native college student was admitted complaining of abdominal pain.

For several years the patient suffered from weekly attacks of nausea occasionally accompanied by vomiting. He felt generally well however, and presented no further symptoms until one and a half years before entry, at which time he passed a stool which was said to have been black. On two occasions thereafter he passed similar stools. One year before admission he began to suffer from dull gnawing pain in the mid abdomen. The pain usually occurred after his midday meal but frequently had no relationship to meals. It did not radiate nor were there any other associated symptoms except for occasional watery diarrhea, which recurred approximately once a month. There was gradual increase in the frequency of the pain until it appeared daily and ultimately two to three times daily. For about three months there was increasing fatigue, lethargy, and some malaise. Five weeks before entry he developed a severe sore throat which over a period of two weeks developed into a "head cold". At this time he consulted a physician who after examining his blood and stools, advised hospitalization.

Physical examination showed a well-developed and nourished man in no distress. No positive physical findings were elicited. The heart and lungs were negative. The blood pressure was 120/65.

The temperature was 99° the pulse 88. The respirations were 22.

Examination of the urine was negative. The blood showed a red cell count of 4,350,000 with a hemoglobin of 70 per cent. The white cell count was 8,300. 67 per cent polymorphonuclears. A proctoscopy was negative but feces removed at this time gave a positive reaction to the guaiac test as did two subsequent specimens.

A barium enema showed normal filling and emptying of the colon. There were no evidences of polyp. The shadow of the spleen appeared to be rather prominent. Several days later an

examination of the esophagus, stomach and duodenum was negative. At six hours the motor meal had reached the hepatic flexure. There was a localized dilatation of the terminal ileum about one foot from the ileocecal valve. The dilated loop lay low in the true pelvis and gradually reduced in size proximally so that within a short distance it appeared to be of normal caliber. Peristaltic contractions of the dilated loop were vigorous but there was no persistent spasm.

On the fourth hospital day a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR. BETH VINCENT. We have here a comparatively young man, twenty nine, whose chief symptom is abdominal pain. He was sent to the hospital where examination of his stools showed occult blood. The history states that one and a half years before entry he may have passed tarry stools. So we have to deal with the diagnosis of a case of abdominal pain with bleeding from the intestinal tract. In all cases of bleeding I think it is well at first to look very quickly at the blood picture and rule out the possibility that you are dealing with a pathological hemorrhage such as we get in thrombopenic purpura. The blood examination given here enables us to exclude that and in passing we note we are not dealing with one of the primary blood diseases.

We also note in the physical examination that the examination made by proctoscopy enables us to exclude one of the most common causes of bleeding, hemorrhoids, and at the same time confirms the fact that the blood was in the stools and thus came from somewhere along the gastrointestinal tract. Such bleeding may indicate either a break in the continuity of the mucous membrane of the gastrointestinal tract as in ulcer, or the ruptures of blood vessels some place in the gastrointestinal tract that have become unduly numerous or dilated. The last we might find in a case of aneurysm of the intestines, a rare lesion and so difficult of diagnosis I think we may dismiss it in this case. Another condition which predisposes to bleeding from ruptured vessels is more common and deserves further consideration that is where the veins of the stomach or esophagus are numerous and dilated on account of obstruction of return of the portal blood. This takes place in two diseases, first in atrophic cirrhosis where the obstruction of the venous return is within the bed of the liver and secondly in obliterative thrombophlebitis of the portal vein or its radicles where the venous return is obstructed in the portal or splenic veins. In both these instances especially in an individual as old as this patient, there is usually congestive enlargement of the spleen. You will notice in this case that the

physical examination was negative and therefore the spleen cannot have been much enlarged, as usually it is easily felt. X-ray suggests some enlargement of the spleen, however. Also, the bleeding in these cases is usually massive. Here the history at one time suggests bloody stools, but there was no vomiting of large amounts of blood.

As to cirrhosis there is no ascites. The individual is rather young for cirrhosis and apparently the diagnosis was not very seriously considered because we have no determination of the functional capacity of the liver. So I think we are safe in saying that this diagnosis is rather improbable.

Continuing then with the ulcers of the gastrointestinal tract, if we begin with the stomach and duodenum we would have to consider malignancy of the stomach and peptic ulcer of the stomach or duodenum. The pain, the gastric symptoms, and the black stools might suggest a peptic ulcer, but you will note that the x-ray is negative. We know that failure to develop the lesion by x-ray in these two diseases, peptic ulcer of the duodenum or stomach, or malignant ulcer of the stomach, is rather rare, so I think perhaps we are justified in saying that this diagnosis is improbable. In speaking of peptic ulcer and bleeding we ought to consider a peptic ulcer in another situation, that is, in relation with a Meckel's diverticulum. As you know, we have those cases. They usually occur in infancy or childhood, may give pain, may give blood in the stools, with a negative x-ray. But most of these cases manifest themselves in infancy or childhood, so I should think this diagnosis was also unlikely.

Passing down into the intestinal tract, if we begin at the other end you will note that the rectum by proctoscopy was negative. I take it also that the digital examination was negative, which certainly would rule out most of the cases of malignancy of the lower bowel. I mean by that, from the rectosigmoid junction downward, and since the x-ray examination of the colon was negative and they did not feel any tumor, it seems to render it unlikely that there was malignancy of the colon. At the same time the x-ray examination of the colon is against ulcer due to colitis and the picture of the individual does not conform to that of ulcerative colitis. It is only fair to say, if this is a surgical lesion, and perhaps because I was asked to discuss it it may be, that most of the low surgical lesions that cause bleeding are located in the colon or terminal ileum. That brings us around to the terminal ileum or cecum. This man has a moderate secondary anemia although x-ray is negative and they felt no tumor. I suppose he could have a malignancy of the cecum, although we can scarcely account for the symptoms of a year and a half with that diagnosis.

He has some temperature, and he might have an inflammatory lesion of the cecum such as we see in tuberculosis, or a lesion of the terminal ileum that is sometimes found, but often hard to diagnose, that is, regional ileitis.

Before making an attempt to settle on any exact diagnosis I think we need an expert's interpretation of the x-ray findings.

DR. AUBREY O. HAMPTON. I have so many films I am lost trying to pick the best ones. We knew this man was bleeding and we looked for a source. We did practically everything, we could including a double contrast enema and a particular search for a posterior wall duodenal ulcer. The double contrast enema was a total washout because the barium did not stick to the mucosa. Here is the gas-filled colon and there is little barium in it. We were able to examine the colon though without any difficulty. There were no redundant loops and you could palpate the whole thing. I think we were quite convinced that there were no polyps. The only positive finding that we had was dilatation of the terminal ileum and this was quite definite. Here is the ileocecal valve, the terminal ileum coming over here, down and around and across and up like that. This loop is quite a way from the ileocecal valve, about two feet, and we were unable to displace it upward although the patient tolerated heavy deep pressure very well. I think it was fixed in that position, deep in the pelvis. One of the films we had showed a small pouch-like thing that was superimposed upon the abnormal bowel here which turned out later to be the tip of the appendix. Of course, that brought up the suggestion that was made, that it might be a Meckel's diverticulum. Certainly at the six-hour examination it was in the location of a Meckel's diverticulum. Later we found that the appendix was unusually low and long, superimposing on the ileum in the midline. But I do not think there was any doubt in any of our minds that the ileum was dilated at that point.

DR. VINCENT. I should think then we might hope to find the lesion in the right lower quadrant and I think perhaps we should exclude an inflammatory or malignant lesion of the cecum and should hope that we would find one of these cases of regional ileitis. If I were going to explore this man I certainly would make a right paramedian incision.

DR. HAMPTON. The x-ray findings were not those of regional ileitis.

DR. VINCENT. In spite of that, I would go over the terminal ileum and cecum and, although they report no polyps, would feel called upon to palpate the colon for polyps very carefully, although as a rule this examination is unsatisfactory. There may be polyps there which cannot be found. At the same time one should feel the liver because if there was a pronounced cir-

robosis of the liver we could make that diagnosis. It may be said that in these cases of bleeding from the intestinal tract where the preoperative diagnosis is so uncertain the exploration is often negative. I do not believe it is so in this instance because otherwise Dr. Mallory would not have presented the case for our consideration.

DR. TRACY B. MALLORY: Have you any comment, Dr. Jones?

DR. CHESTER M. JONES: I know what he had but there are certain points that I should like to make. I think it is interesting in the first place because this student reported to one of the men over at Harvard a year ago and said he was fatigued and on examination nothing was found. Fatigue was the outstanding symptom. He came back this time with the same symptom. At that time a blood was done and the hemoglobin was said to be seventy but it was seventy Sahli and whoever did it paid some attention to it. Seventy per cent Sahli in a young man of twenty-nine represents a definite but rather slight anemia and on the basis of that a careful study was made of this man in the office over at Cambridge as to the cause of his anemia. It was thought not to be a primary blood disease but secondary to loss of blood and stools were taken and a positive guaiac found. I think that represents an intelligent attempt to answer this patient's symptoms in the first place. One of the things not brought out in this history is the fact that this boy's pain was usually merely discomfort but on one or two occasions was sharp, localized below the umbilicus in the midline, very strongly suggestive of small bowel pain as contrasted with that due to disease of the stomach, duodenum or large bowel. He persisted in localizing that pain always in the same place. I proctoscoped him and the examination was negative except that we did get fecal material coming down from above showing a positive guaiac test. That was important because it showed that there was bleeding from above. The x-rays were taken and Dr. Hampton discussed them with me. We felt because of the local ileal dilatation, the symptoms, and because of the bleeding that this might represent the very unusual picture of Meckel's diverticulum bleeding in an adult. It was on this basis that we explored, with a diagnosis of Meckel's diverticulum, and we expected to relieve it.

A PHYSICIAN: How often do they show by x-ray?

DR. HAMPTON: I thought I was going to be the first one in the hospital to make the diagnosis by x-ray and I thought right up to the second note that this was due to a Meckel's diverticulum but since I could not demonstrate the diverticulum I did not think I had enough to make a diagnosis. It was with the aid of the clinical findings, that Dr. Jones mentioned, that

together we were convinced it was a Meckel's diverticulum. At the second examination I hunted for the diverticulum particularly, and I could not find it. The diagnosis by x-ray has been reported once in the literature.

PREOPERATIVE DIAGNOSIS

Meckel's diverticulum

DR. BETH VINCENT'S DIAGNOSES

Regional ileitis?

PATHOLOGIC DIAGNOSES

Meckel's diverticulum

Chronic ulcer

PATHOLOGIC DISCUSSION

DR. MALLORY: This is a photograph of the specimen which was removed. You can see this wide diverticulum projecting to the left of the resected section of ileum. At the base of the diverticulum just at the junction with the small intestine, there is an area which is discolored and shallowly ulcerated. The specimen had aroused so much interest that it received the treatment which sometimes occurs to particularly valuable specimens. It was taken out of the routine to be photographed and shown at various clinics, and by the time we got it back it was no longer of any use for histologic purposes. We did manage to get a single block for microscopic examination which shows the area of ulceration but does not show any gastric mucosa. The section was taken from the immediate neighborhood of the ulcer and it is the rule in these cases that the ulcer is not found in the area where the gastrointestinal mucosa is present but in the immediately adjacent intestinal type of mucosa. So there may perfectly well have been gastric mucosa here even though we did not demonstrate it. On the other hand I rather doubt if that was the case, however, because the ulcer does not look like a peptic ulcer. A peptic ulcer has microscopically a very characteristic appearance. The surface is usually quite clean, almost free from leukocytes, and then there is invariably in the active ulcer a superficial zone of so-called fibrinoid necrosis which appears in ordinary sections as a broad red hyaline layer. I have never seen an active peptic ulcer in which this was not present and there is no suggestion of it here. So I am inclined to think that this ulcer was infectious and not peptic in nature. If that is the case it might explain why he has gone well into his late twenties before developing symptoms instead of having hemorrhage from his diverticulum in the first and second decades as is the common story.

DR. McKIRTRICK: How high above the cecum may a Meckel's diverticulum be found? How much of the terminal ileum ought one to explore?

DR. MALLORY: I am not able to answer that

definitely. They say that a yard is the common spot but I am quite sure it can go higher, how much higher, I do not know.

A PHYSICIAN How much of a lumen did it have? Could you stick your finger in it or not?

DR MALLORY Yes, very easily. It is characteristic that they almost invariably have a wide lumen as compared with an appendix, very nearly as great as that of the small bowel.

DR HAMPTON Is the mucosa in the diverticulum the same as in the terminal ileum, does it show the same gross pattern?

DR MALLORY It varies a great deal from one diverticulum to another. It should be approximately the same as the ileum. In some cases, however, a very large proportion is made up of gastric epithelium.

A PHYSICIAN What percentage of cases of Meckel's diverticulum contain gastric epithelium in your experience, Dr Mallory?

DR MALLORY I cannot answer that. It was supposed to be a very rare phenomenon until about five years ago, when the attention of surgeons working particularly in children's hospitals was called to the fact and on checking back they found that a very large proportion of these cases showed it. I do not know of any systematic study of the symptomless Meckel's diverticula that are so commonly found at autopsy. One and a half per cent of individuals have a Meckel's diverticulum. I do not know if any one has checked them to see if they contain gastric mucosa.

CASE 22102

PRESENTATION OF CASE

A sixty year old white Canadian woman was admitted in a semicomatose state.

Eight weeks before entry she went to care for a sister who was dying of pulmonary tuberculosis. A week later she became ill with pain, primarily in the left chest, but later upon the right side also. She had at the same time chilly sensations and some fever, and a physician told her she had pneumonia. Early in the course of her illness there was slight jaundice, but this disappeared in a short time. Her appetite was poor, and there was marked nausea but no emesis. Her mind "wandered" a great deal during her illness. She continued to run a febrile course for two weeks, at which time her tongue was so dry that three hypodermoclyses were given. Subsequently edema appeared, first upon the arms and feet but gradually involving the entire body except the face. The swelling remained unchanged upon the trunk and lower extremities but varied in severity in the arms, first affecting one and then the other. She required daily catheterization from the onset of her illness.

She had had rheumatic fever at the age of twelve years.

Physical examination showed a well-developed woman lying upon her back, tossing her head from side to side and moaning. Her respirations were Cheyne-Stokes in character. The skin was loose, dry, and flabby. The tongue was dry, swollen, and brown. The upper sternum was quite prominent. The heart was slightly enlarged and the sounds though regular were of a rather poor quality. A third heart sound was audible at the left border of the sternum and a systolic murmur was heard at the apex. Moist râles were present in the left lower back but no dullness was elicited. The abdomen was slightly distended and tympanitic. There was slight tenderness in the epigastrium with a vague sensation of an underlying mass. Marked edema of the right arm, both lower extremities, and the trunk was observed. Small decubitus ulcers were noted over the sacrum and right heel. The knee jerks were sluggish and the ankle jerks were not elicited.

The temperature was 99°, the pulse 100. The respirations were 32.

Examination of the urine showed a specific gravity of 1.006 with a trace of albumin. The sediment contained many white blood cells and an occasional red blood cell. The blood showed a red cell count of 3,340,000, with a hemoglobin of 75 per cent. The white cell count was 26,600, 91 per cent polymorphonuclears. The serum protein was 4.3 milligrams per cent. The non-protein nitrogen of the blood was 53 milligrams per cent and the sugar 91 milligrams per cent. A lumbar puncture showed an initial pressure of 230 with the head slightly elevated. The fluid was clear, colorless, and contained 73 red blood cells but no white blood cells. The total protein was 57 milligrams per cent and the ammonium sulphate test was positive. A Hinton test was negative.

X-ray examination showed partial obliteration of the costophrenic angles. There were bands of dullness along each axillary line from the apex to the diaphragm. These bands were thicker in the region of the right interlobar septum and upper portion of the left lung. The lung fields showed diminished radiance as the result of a rather coarse, hazy mottling. The mottling was most dense in the region of the right upper lobe and interlobar septum between the upper and middle lobes. The right lung seemed smaller than the left and the intercostal spaces were narrowed on this side. The heart and mediastinum were slightly displaced to the right.

On the day following admission her temperature rose to 101°, but there was no change in her general condition. Despite the administration of transfusions she went rapidly downhill and expired on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR. MAILES P. BAKER The gist of the problem here lies in the question of etiology of what on admission must have seemed a case with the so called "slow nervous fever" of the old clinicians. The history in such a situation must of necessity be scanty in detail and only partly reliable and so sick was she that there was no time for confirmation of certain laboratory examinations the results of which would warrant repetition.

We are dealing with a woman of sixty who has had a fever for at least two weeks, and probably seven who is brought to the hospital in a restless delirium with signs of dehydration and edema of the trunk and extremities, but not of the face, the latter so typical of renal edema. As for the details of her illness we do know that the infection began with pain first in the left chest and later on the right side, presumably pleural pain. Of the importance of the such jaundice mentioned we cannot judge and it is probably hazardous to emphasize this.

It is interesting that from the very beginning she was confused mentally and required daily catheterization for incontinence in all likelihood.

The appearance of edema varying in severity in the arms according to which side she lay on bespeaks a plasma protein deficiency.

It seems fair to wonder whether this fatal infection did not follow on a period of relative ill health with impaired appetite and protein intake, but such must be only conjecture.

The physical examination is noteworthy in that there is no localization of the infection other than such evidence as there is of possible pulmonary infection in the left lower lobe. The absence of ankle jerks is not to be wondered at in such a depleted individual. We have no other evidence of a peripheral neuritis.

The increased respiratory rate is worthy of comment and directs attention toward the possibility of a more widespread pulmonary involvement than one would conclude from the physical examination.

Laboratory tests reveal the picture of a cystitis. Thus may well be the result of repeated catheterization. She was anemic. One would hesitate to draw any conclusion from one hemoglobin determination of seventy five per cent with such a low red blood cell count. The leucocytosis is important. The serum protein level is what we would expect with the degree of edema noted and seven weeks of fever and neglect. The nonprotein nitrogen we may interpret as evidence of dehydration rather than renal insufficiency necessarily. It is not the urinary sediment of a progressive glomerulonephritis nor have we had the retinopathy of such. The spinal fluid shows findings that are

difficult to interpret. The slightly elevated pressure and rise in protein are compatible with the presence of an area of degeneration adjacent to the subarachnoid space in an elderly person with tiny cerebral thromboses. It is strange that she should have as many red blood cells as this without any white blood cells. An increased spinal fluid protein is occasionally found in elderly people with cerebral arteriosclerosis and the main information to be drawn from this wisely done lumbar puncture is that the woman did not have a subarachnoid hemorrhage which is sometimes the cause of a "typhoid" state, and protracted fever.

Prior to the evidence brought to hand by the chest x ray several possibilities might come to mind, among them military tuberculosis, a protracted case with recrudescences, of typhoid fever which had begun with an initial bronchitis, or gone on to some complication such as a pyelonephritis with colon bacillus infection. Were this a neglected undiagnosed case of typhoid fever there might have been a crural thrombosis that had suppurated or suppurating mesenteric glands that had given rise to a leucocytosis. It is well to remember that military tuberculosis and typhoid fever may occur together or that pulmonary tuberculosis may manifest itself in the course of convalescence from typhoid fever and the fact that typhoid fever begins with pleuritic symptoms simulating the effect of rupture of a caseous subpleural lymph node into the pleural cavity is of course an old story.

The fact that she had had rheumatic fever early in life makes one consider the possibility of a chronic ulcerative endocarditis only to abandon the possibility, for there have been no embolic phenomena for one thing.

Soma cases there have been of obscure deep seated osteomyelitis undiagnosed until postmortem, but without localizing signs this must have seemed unlikely.

I recall seeing one case of delirium with similar fever and dehydrated state, a woman who showed on physical examination only the signs of an acute bronchitis. This was the first of the cases of tularemia with pneumonia recently reported by Bernstein in the Hopkins Bulletin.

Her chest x ray as I recall it, revealed nothing of a localizing nature. This brings us to a discussion of the x ray of this patient's lungs which seems to me to limit the diagnostic possibilities. The x ray picture showing haziness most dense in the region of the right upper lobe but involving both lungs, is consistent with the presence of a military tuberculous infection. I gather that the shadows are not so sharply demarcated and dense as in the accidentally found healed stage of military tuberculosis, nor are the shadows those of the larger nodules, more round, less uniform that are char-

characteristic of carcinomatosis of a milary type. It is not the picture of lymphangitis carcinomatosa rarely seen in association with a scirrhus carcinoma of the stomach which has metastasized to perivascular lymph channels in the lungs. There is not the predilection for lower lobe involvement of silicosis. The smaller right lung field is I suppose due to partial bronchial occlusion, as with an older peribronchial fibrosis or a newer necrosis of the mucous membrane. The x-ray, in the absence of evidence of carcinoma elsewhere, seems to me to point strongly to the diagnosis of milary tuberculosis which is a self-propagating septicemia occasionally running as long a course as this, seven to eight weeks. The onset with pleuritic pain, the typhoidal course, the rapid respiratory rate, the leucocytosis, all are consistent with such a diagnosis. It is interesting to note that in the earlier Cabot Case Histories milary tuberculosis was often missed in the antemortem diagnosis, but the x-ray examination here is an added aid in the diagnosis and confirms my suspicion that it is of a milary tuberculosis that this woman died.

CLINICAL DIAGNOSES

Acute and chronic nephritis with edema
Unresolved pneumonia
(? Milary tuberculosis)
? Brain abscess
Secondary anemia
Malnutrition

DR MYLES BAKER'S DIAGNOSES

Milary tuberculosis
Cystitis
Cerebral thrombosis

ANATOMIC DIAGNOSES

Organized thrombo-endarteritis of the pulmonary arteries
Pulmonary fibrosis
Emphysema
Pyelonephritis, bilateral
Cystitis
Chronic pancreatitis with fat necrosis
Hydrothorax, right
Pleuritis, chronic fibrous, bilateral
Ascites, slight
Endocarditis, terminal, mitral
Arteriosclerosis Aortic, moderate
Decubitus ulcers, sacrum and heel.
Perisplenitis

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY This is a type of case which it is hardly fair to put up to the clinician for differential diagnosis inasmuch as when the autopsy has been done and all the

microscopic slides carefully studied the pathologist is still unable to make a diagnosis. It belongs in a group of pulmonary cases which for the moment we are calling, simply because a name is necessary for filing, pulmonary fibrosis. It is obvious that this is not a disease but a condition of the lungs which can be produced by many diseases. The healed stage of a diffuse tuberculosis would, for instance, produce such a result. Organizing pneumonias not infrequently are another cause. Fibrosis developing in and about the lymphatics, such as we see in silicosis, represents another type.

This particular case belongs to a still different category. There are numerous patches of dense fibrous tissue in which the remnants of the elastica of the alveolar walls can still be seen. The picture is closely similar to that produced by organizing pneumonia. There is, however, another lesion present which I believe is primary rather than secondary. Nearly all the medium-sized and small pulmonary arteries show extensive organized and recanalized thrombi within their lumina. These lesions are for the most part old and inactive. A few lobules of lung tissue show fresh changes more suggestive of infarction than of pneumonia, and, in some of these, early organization is evident. I believe this case probably belongs to the group of diffuse thrombo-endarteritis of the pulmonary arteries. The possibility of multiple small emboli is difficult to exclude absolutely but no source for emboli was discovered in the remainder of the autopsy. The process is evidently one of great chronicity, of much longer duration than the patient's story would indicate. The lungs show the usual results of extensive pulmonary destruction in the form of marked emphysematous dilatation of the persisting alveoli. The heart weight was within normal limits, but the right ventricle measured 6 millimeters, a slight but definite cor pulmonale.

The clinicians in the hospital did not have a much more definite idea of the diagnosis than Dr. Baker. They had the advantage of personal consultation with the roentgenologist, who stated definitely that he did not believe the lesions were tuberculous although he could not rule out that possibility. The patient was discharged with a death certificate reading: ? unresolved pneumonia ? milary tuberculosis. They believed that she probably had as well an acute and chronic nephritis with edema.

We found at autopsy slight injection of the renal pelves and slight pallor and thickening of the cortex. Microscopic examination showed a moderate grade of diffuse pyelonephritis. A few minute fresh vegetations were found upon the mitral valve. We considered this, however, only a terminal incident probably of little importance in the course of her disease. We unfortunately were unable to examine the head.

IVAN PETROVITCH PAVLOV

THOSE who attended the XVth International Physiological Congress in the Soviet Union last August will rejoice in retrospect that Pavlov was spared to preside over that memorable scientific meeting. He had been several times ill some ten months ago an attack of pneumonia caused his life to be despaired of, but it almost seemed that the Fates had decreed he should live until the Congress was over. He presided with great verve at the opening meeting in the Uritsky Palace, he attended the subsequent scientific sessions, he entertained many of the delegates at luncheons and dinners during the week of the Congress, and he presided again at the official banquet at Detskoye Selo. On this occasion the gifted chiefs of the old régime inaugurated the sumptuous feast by preparing an effigy of Pavlov in ice. This striking likeness of the fiery old gentleman headed a procession of 150 waiters bearing delicacies through the great banquet hall of the Catherine Palace. All this seemed to exemplify the final triumph of an extraordinary career which was to come to an end at Moscow February 27 1936. Unhappily

the last months of Pavlov's life were immeasurably saddened by the death on October 29, 1935, of his devoted son, Vs. I Pavlov who succumbed to an inoperable carcinoma of the pancreas.

Pavlov giving the opening address August 3 1935 at the Physiological Congress in Leningrad.

Ivan Petrovitch Pavlov, the left handed son of a village priest, Peter Dmitrievitch Pavlov (also left-handed), of the district of Rjāzan in Russia, was born September 14, 1849. After a modest preliminary education in a local church school, he later attended a theological seminary where through the Russian translation of G. H. Lewes' (George Eliot's consort), *The Physiology of Common Life*, he became interested at the age of fifteen in biological science. Relinquishing theology, he was admitted in 1870 to the University of St. Petersburg where he studied under Mendeleev. On completing work for a scientific degree he entered the Military Medical Academy, receiving his qualifications in 1879 and his M.D. in 1883. As an assistant to S. P. Botkin, a clinician he was allowed to carry on animal experimentation and five years later received an appointment corresponding to "Privatdozent" in Physiology at St. Petersburg. In 1880, though wholly impecunious, he married Serafima Karchevokaya who, fortunately for science, was a self-sacrificing and devoted woman. She bore him four children (two left-handed) and participated in his life until the end.

The years 1884-1886 were spent on a "fellowship" in Germany where he studied under Ludwig and Heidenhain, it was during this period that he made his observations on the output of the isolated heart (published in 1887). Before going to Germany he had studied the factors involved in the regulation of the normal blood pressure of a dog, recognizing at this early period that anesthetics and emotional disturbances affected many physiological functions and mistaking that no isolated physiological process could be studied unless *all other func-*

tions were kept constant. He therefore trained his dog to allow, without anesthesia, the insertion of a cannula into a small superficial artery on the inner side of the knee joint and to remain quiet while the blood pressure was recorded. In these circumstances he was able to study the effect of ingestion of food, injection of large quantities of water, etc., upon the level of the blood pressure. These studies, carried out in 1878-9, formed the basis of those memorable investigations which were to be the foundation of his later scientific recognition.

In 1890 the Institute of Experimental Medicine was built at St. Petersburg by Prince Oldenburg, and Basil von Anrep, pharmacologist and father of the present professor of physiology at Cairo, was made its first director, in 1891 Pavlov was asked to assume responsibility for the physiological departments of the Institute. He retained his post for many years, though in 1897 he also became Professor of Physiology at the Military Medical Academy, and when in 1907 he was made one of the four scientific members of the St. Petersburg Academy, he found himself with a third laboratory to direct. Throughout his life he continued association with all three institutions, and some years ago, through the generous support of the Soviet government, he was given a fourth and very elaborately equipped laboratory at Koltooshy, some 30 miles outside Leningrad. There in the quiet atmosphere of a small country village conditioned reflex studies were carried out under almost ideal conditions by a group of selected and highly trained collaborators. There, latterly, Pavlov lived some six months of the year in constant association with his favorite students and with his family.

The work for which Pavlov is best known, and for which he received the Nobel Prize in 1904, is that concerned with the physiology of digestion. As early as 1879 he had published three papers on pancreatic secretion, one of which described a new method, similar to that originally used by de Graaf, for making a pancreatic fistula. Not until 1888, however, did he devote his time consistently to the study of digestion. In that year he showed that the vagus nerve was secretory to the pancreas, and in 1889 a paper from his laboratory described the secretion of the gastric juice (*Centralbl. f. Physiol.*, 1889). Here we find the first description of the Pavlov method for obtaining pure gastric juice. Fistulous openings were made in the stomach and also in the esophagus. Food was introduced through the lower end of the esophagus, or into the stomach directly. The animal must have recovered fully from the operative procedure necessary to establish these fistulae before observations could be made. It was recorded by the late Professor Starling (*Nature*, 1925, p. 2) that Pavlov took the operated

animals into his home where they were cared for by his wife and four children until full recovery. In the animal with gastric fistula Pavlov observed that after it saw or smelled food, an abundant flow of gastric juice occurred, designated "psychic secretion." The response evidently depended upon reactions integrated at the cortical level, and in later studies he and his students were able to show that removal of the cerebral cortex abolished the response and that, when present, it was mediated by the vagus nerve since section of this nerve also destroyed the reaction. Peripheral stimulation of the vagus evoked gastric secretion similar to that produced by psychic stimuli. Pavlov's observations on gastric secretion were published in German in 1898 under the title, *Die Arbeit der Verdauungsdrüsen*. This was soon translated into French and into English.

Study of the response of the gastric mechanism led Pavlov logically into the field of higher nervous function. In the hands of Sherrington and Magnus the more simple somatic reflexes subserving posture and phasic movement had been analyzed in some detail. Pavlov set himself the problem of analyzing the highest levels of nervous function in similarly objective terms. The higher adjustments underlying memory and educability depend upon the cerebral cortex. Pavlov conceived the fertile thought that the gastric reactions just described might be used as an index of cortical function. If food is actually introduced into a dog's mouth, saliva and gastric juice flow, the response varying in extent with the intensity of the stimulus. Reactions of this character Pavlov designated as "unconditioned." If, however, the presentation of food were regularly heralded by the sound of a bell, or by some other sensory stimulus, the animal soon comes to associate the particular sensory experience with the subsequent acceptance of food. Such a preliminary stimulus was designated "conditioned", and the response which followed, even though the food were not actually presented, a "conditioned reflex." Pavlov believed that such conditioned reflexes were dependent upon the integrity of the cerebral cortex. Consequently, through the analysis of reactions of this character, he was able to investigate functions of the cortex as a whole, as well as reactions of discrete areas of the cerebral mantle. Pavlov gave a preliminary account of these studies in London in 1906. Later reports were published in the Russian language, but not until 1927 when Gleb von Anrep (the son of his former master), translated Pavlov's lectures, did the physiological world have an adequate conception of Pavlov's doctrines and of the experimental evidence on which they were based.

Pavlov came to this country on several occasions the last visit being in 1929 when he attended the International Psychological Congress in New Haven, and the International Physiological Congress at Boston. Pavlov's public appearances in 1929 were made memorable and vivid by Anrep's remarkable translations of his utterances. One such occasion in Boston was described at the time as follows:

'Before a small and select group in one of Cannon's side rooms we had Pavlov serving up his latest ideas of inhibition in relation to neuroses, hot from the griddle. Vivid alert gesticulating the old man poured out his Russian phrases, like a mitrailleuse never missing fire, directing his attention meanwhile chiefly to Anrep who sat calmly alongside smoking innumerable cigarettes. Pavlov would suddenly stop and point menacingly at Anrep who possibly would ask him a question or two to make sure of his ground—indeed even interrupt him. Pavlov, moving his watch and chain along about six inches farther on the table in front of him would slump down in his chair, shifting his ischial tuberosities to one side or the other—whether because the chair was hard or because this was one of his reflexes, I am not sure. Anrep would then begin always composedly, and give a most brilliant and concise presentation in English of what had gone before. Pavlov then picking up the thread again and continuing. This went on for an hour and, except for the intrusion of a few belated guests who crowded into the room, one could have heard a pin drop.'

The conditioned reflex has become the principal experimental means for the analysis of cerebral function. The physiologist has used Pavlov's method, and applied it to many fields of study. Psychological laboratories, especially in this country, have also adopted and elaborated the method, but they have placed a more restricted interpretation upon the results obtained. Evolutionary study of cortical function indicates that some reactions are more highly encephalized than others, in consequence of this, lower animals such as cat and dog, may exhibit primitive conditioned reactions after their cerebral hemispheres have been removed. Studies of visual function in monkeys indicate that condition reflexes involving light perception may be demonstrated after the occipital cortex is destroyed, but those reflexes dependent upon *object* vision disappear when this part of the forebrain has been surgically ablated. Granting the modifications arising out of such comparative psychological study, the broad conceptions of Pavlov remain the foundation of modern analysis of cortical function. The reflex, as observed in

the spinal cord, becomes the unit from which all higher reactions are ultimately elaborated and the cerebral cortex differs in no essential respect, except that of complexity, from the orderly mechanism of the spinal animal. Such was Pavlov's thesis, and however much critics may quibble over the details of Pavlov's individual theories such as that of internal inhibition, the fact remains that he gave the world a new approach to a complex problem, and by so doing brought order out of chaos. Pavlov was indeed one of five or six individuals of the last generation who caused mankind to think in new terms. Like Freud he created a new horizon, but unlike Freud he remained wholly objective in his mode of collecting scientific data.

The studies of Pavlov which place the reactions of man and animals on a common plane appealed to the leaders of the Soviet Government as a creed. The Orthodox Church had been overthrown, and in its place an objective science of human behavior came to be uppermost in the minds of those who directed the destinies of the new political régime. Pavlov thus became in spite of himself the preceptor of a new social order; and though he criticized the political dicta of the Soviet he was accepted, protected and given recognition of a character never before accorded to a scientific man by any government, and whatever may happen to science in Russia, the world cannot easily forget that Ivan Petrovitch Pavlov was honored and handsomely supported by a political regime for which he had little sympathy.

REFERENCES

In February 1936 just twenty years ago, Pavlov's death was announced in a full page obituary appearing in the columns of the *Lancet* (Feb. 18, 1936) 487-423. Significantly conditioned reflexes are not mentioned in this premature notice. This phrase of Pavlov's work had not attracted the attention of English readers. Other sources material concerning his life are as follows: E. H. Starling, *Voice* 1928, 118:1-2; W. H. Grant, *Biographical sketch in Lectures on Conditioned Reflexes* (1929) pp. 11-21; Starling, O. W. Arch. Neurol. Psychiat. 1935 32:1535-1557. This last contains references to other source material.

Note: The spelling of Pavlov's middle name Petrovitch was preferred by him.

THE MASSACHUSETTS PNEUMONIA CAMPAIGN

THE five year state-wide Pneumonia Study and Service carried out by the State Department of Public Health with the financial support of the Commonwealth Fund of New York terminated at the close of the year. This enterprise constitutes a notable achievement in public health practice, and an achievement rich in results for the practitioner of medicine.

From the scientific part of the program have come improved methods for the production of serum. Preparations of Types I and II serum of higher potency, more accurately standardized, have been made freely available. Tests for the physiological action of the product have been

devised with a constant lessening of undesirable reactions in the patient, while, through technical refinements, the cost of the serum has been appreciably lowered

In the field study, new facts have been learned as to the prevalence of the various serological types of pneumococcus responsible for lobar pneumonia, and the fatalities caused by these different types. More than ten thousand sputum specimens have been examined, affording an opportunity for a comparative study of the different methods of type-determination. Physicians throughout the State by means of lectures, addresses, conferences and the free distribution of reprints of recent publications have been made familiar with the latest and best practice in the bacteriological and clinical diagnosis, and the medical, surgical and nursing treatment of this disease. Special, intensive, one-day courses covering all the phases of pneumococcal infection were given by recognized authorities at the Harvard Medical School, and many Massachusetts physicians attended these lectures as guests of the Pneumonia Fund. Nearly one hundred technicians from many state, city, county and private hospitals, and local health departments were invited to Boston and given laboratory instruction in methods for the determination of pneumococcal types. By this plan, stations have been established in various localities where identification of the infecting pneumococci in sputum, blood and other body tissues can be made with little delay.

Altogether, sixty-five hospitals were selected as centers of special, detailed study of serum treatment, and these hospitals served as depots from which serum was given to physicians co-operating in the study. Collaborating physicians were appointed in all the districts to visit patients with practitioners desiring advice on diagnostic problems or on the details of serum treatment, the fees of these collaborators being paid either by the patient or from the special Pneumonia Fund. Thus, serum and expert counsel were furnished to physician and patient. Special case report forms were supplied to all those using the serum. In this way uniform records of nearly one thousand cases of lobar pneumonia were collected. Included in this is the largest single series of serum-treated Type I cases ever assembled. Some seven hundred cases of lobar pneumonia receiving no serum were investigated.

These records contain valuable information concerning many of the phases of the serum treatment of lobar pneumonia. Their large number permits reliable statistical analyses, and the study already made of these case histories furnishes a sound basis for the appraisal of specific serum treatment. When antipneumococcal serum was administered in sufficient amount

within the first four days of the disease, there was a reduction of fifty-six per cent in the fatality rate of the Type I cases and of thirty-four per cent in those cases due to a Type II infection. The results of this five-years' experience have been condensed into a handbook for physicians on lobar pneumonia and serum therapy, which in compact and concise form tells the physician the essential details of the diagnosis and treatment of this disease. We are promised that within the year compendious reviews of the existing literature on Pneumococcus and lobar pneumonia will appear.

The State Department of Health will continue its studies of Pneumococcus, of serum production and of pneumonia and allied infections, and Types I and II antipneumococcal serum will be distributed under certain desirable stipulations, free of charge to physicians.*

We have selected for mention only the most immediate and conspicuous results of this soundly planned and ably executed program. Its method of operation and its manner of administration, enlisting as they have, the hearty co-operation of the members of the medical profession, and with its emphasis on study and its generous service, may well be taken as a model for other public health programs. Already the Connecticut Department of Public Health is distributing Types I and II antipneumococcal serum free of charge to those who cannot afford to pay for it and at cost to those who can, and the City Department of Health of Detroit is now supplying serum to its physicians. The State Medical Society and the Public Health Department of New York State, with the financial aid of the Commonwealth Fund and the Metropolitan Life Insurance Company, on the first of the year inaugurated a somewhat similar service.

We congratulate the Massachusetts Department of Public Health upon its distinguished achievement and voice the appreciation of Massachusetts physicians of the generosity of the Commonwealth Fund in supporting the Pneumonia Study and Service.

*See p. 219 of our issue of January 30, 1936. Vol. 214, No. 5.

The Massachusetts Medical Society

THE SECTION OF TUBERCULOSIS

THE Officers of the Massachusetts Medical Society have requested that this year the programs of all the sections be made of especial interest to the physician in general practice. With this in mind the Section of Tuberculosis is planning a program quite different from those which have been given in the past. It has been decided to make the session a definitely clinical one with presentation of cases and a discussion of the

treatment of pulmonary tuberculosis as it develops at different ages. This discussion is to be of the sort which will be of value to the general practitioner rather than to those who are doing special work in tuberculosis. The papers are to be arranged as follows

(1) Presentation of a case history of pulmonary tuberculosis in both infant and child. With discussion of treatment. Dr Clement A. Smith, Boston Children's Hospital

(2) Presentation of a case history of pulmonary tuberculosis in an adolescent. With discussion of treatment. Dr Roy Morgan, Superintendent of the Westfield State Sanatorium

(3) Presentation of a case history of pulmonary tuberculosis in an adult. With discussion of treatment. Dr John B. Hawes, 2nd Boston

Dr Edward D. Churchill, Professor of Surgery at the Harvard Medical School will be present to discuss the cases from the surgical standpoint, and Dr Hugh Hare, Roentgenologist at the Middlesex County Sanatorium, will be ready to discuss various features of the x-ray films

The formal presentation of each case will be limited to twenty minutes so that there will be ample time for questions and discussion from the floor, and it is the hope of the officers that this part of the program will be of especial value. For safety's sake each discussion will be limited to three minutes

A meeting of this sort is somewhat of an innovation for the annual session of the State Society, and it will be interesting to see whether such a program can be successfully carried through

PREECLAMPSIA AND ECLAMPSIA

Terminology and Definition The term 'Toxemia of Pregnancy' should be abandoned

A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

in favor of Preeclampsia and Eclampsia. These are the same condition except in degree.

Twenty-five per cent of all maternal mortality in the United States is accounted for by this condition.

Etiology Hofbauer (*Am J Obst & Gynec* 26 311, 1933) showed to his satisfaction that the relationships between foreign protein (i.e., foreign to the body economy except in pregnancy) and the internal secretions, especially the posterior pituitary, result in preeclampsia and eclampsia. It is generally considered that certain steps in his reasoning remain to be proved or checked. Acceptance of his theory of etiology varies greatly among prominent workers in this field. It would perhaps be fair to state that many of the data involved are impressive, but that since certain links in the chain are weak his thesis is not in general considered proved. George van S. Smith seems to show a relationship between the pituitary and the eclamptic state, and quite likely it is along the endocrine line that a cause will be found. Considering the difficulty of concentrating the endocrines, the expense, and the large dosage presumably required, direct endocrine therapy seems a distant possibility, even if an endocrine relationship shall have been proved. For the present then we must fall back on the old idea, namely that the only sure known etiology of the eclamptic state is pregnancy, present or recently past.

It is now apparent that the group of cardiovascular and nephritic conditions which may be called, for the sake of simplicity, essential hypertension and suspected chronic glomerulonephritis are best viewed in relation to the eclamptic state from the standpoint of secondary etiological factors. In 1927 Corwin and Herrick (*Am J Obst & Gynec* 13 617, 1927) (*J A M A* 88 457, 1927) suggested this and in 1935 proved it by necropsy findings checked against a long period of clinical observation (*Arch Int Med* 55 643, 1935). The exact and percentage relationship between these conditions and the eclamptic state has yet to be worked out in a great group of cases followed to autopsy, but a more or less general acceptance of this point of view is already apparent. As a basis for an up-to-date understanding of these medical conditions we have found the book "Hypertension and Nephritis" (3rd Edition) by Fishberg invaluable.

In concluding the question of etiology it seems wise to stress again two other correctable and often neglected factors in the production of the eclamptic state. These are obesity with uncontrolled weight gain in pregnancy, and focal infection. *A physician neglects his patient if he fails to note and to attempt to control her overweight at each prenatal visit quite as much as*

though he failed to observe her blood pressure and urine. The matter of focal infection needs no further emphasis.

Signs and Symptoms The well-known signs and symptoms of relative hypertension, albuminuria, edema, especially of the face, sudden weight gain, blurring of vision, nausea, and vomiting, constitute premonitory signals and sufficient cause whenever possible to hospitalize the patient. Torpor and irritability, mental or motor, constitute the final danger signals. Epigastric pain, convulsions, coma, and death within thirty-six to forty-eight hours too frequently constitute the termination of the eclamptic state. It is important to note that this condition progresses at different rates of speed, i.e., slowly in a matter of days or even weeks, rapidly in a matter of hours, or very rarely, fulminating—without warning. Since this is true, a weekly urine examination and a blood pressure and weight record every two weeks is the minimum requirement for proper prenatal care. Even then some "quick cases" will get off to a long start before detection. We have come to feel that borderline diastolic pressure, 90 to 100, is an important prognostic sign. If a patient shows any sign or symptoms and cannot be hospitalized for observation for economic reasons a daily urine specimen and a blood pressure reading every other day constitute the minimum requirement.

Treatment Eclampsia, usually defined for simplicity as preeclampsia with the addition of convulsions, carries about ten times the maternal mortality rate of preeclampsia in this region. The relative fetal mortalities—if the child is over thirty-two weeks—is probably even greater in the two conditions. In 168 consecutive cases of eclampsia investigated recently we find a maternal mortality of nearly 40 per cent in emergency cases, nearly 20 per cent in observed cases, a combined mortality of just under 25 per cent. These cases occurred over a period of twenty years and were treated in a variety of ways, largely on conservative principles. No improvement in results can be demonstrated because of changed detail of treatment in these cases. *Therefore, since the maternal mortality in preeclampsia may be set at 25 per cent it seems reasonable to assert that to date the primary principle of the treatment of the "eclamptic state" is to empty the uterus, by the gentlest means and after getting the patient in her best possible condition by the well-known accepted sedative eliminative treatment, prior to convulsions.* This is usually satisfactorily accomplished by rupture of the membranes with or without the guarded use of a pressor-principle free oxytocic. Occasionally abdominal cesarean section may be considered, but should be avoided if possible, since severe

preeclampsies are poor surgical risks. Nice judgment based on experience and a careful weighing of all factors including the preservation of the frequently premature baby are necessary to make this decision wisely, especially as it is a striking fact that a study of maternal mortality statistics in Massachusetts year after year invariably shows a notable list of combined "Toxemia—Cesarean Section—Peritonitis" deaths. It must be borne in mind that abdominal cesarean section in preeclampsia does not guarantee a living baby especially if it be premature. Clifford has shown a 45 per cent mortality in infants under five pounds in cesarean section done for this condition, a mortality of 27 per cent in the infants in this group that weighed from 4 to 5 pounds. Plass has shown recently a 6 per cent maternal mortality in sixty-seven sections for preeclampsia done throughout Iowa in 1930-1932. J. A. Smith of Boston reports a similar series of fifty-seven cases with a maternal mortality of 53 per cent. On the other hand the writer, paying especial attention to anesthesia with the omission of all preoperative medication and a technique of operation which exposes the baby to practically no anesthetic and the mother to very little has performed forty-five sections for severe preeclampsia with the death of a single mother a rate of 2.2 per cent. Of the babies in this series twelve weighed between four and five pounds and were all discharged well from the hospital. Babies under four pounds, seven in number were all less than twenty-eight weeks and all died. Babies over five pounds, twenty-five in number, all lived but one. The mother of this baby had preliminary medication including morphine forty-five minutes before operation. It may be added that four of the forty-five preeclamptics developed eclampsia. So perhaps it may be concluded that with an unfavorable cervix, abdominal cesarean section under special precautions has a place in the treatment of preeclamptic toxemia.

Treatment of Eclampsia It is the generally accepted opinion that some one or other of the so-called conservative routine methods of treating the eclamptic state once the patient has developed convulsions (or coma) gives far better results than active obstetrical intervention. Further it is generally stated that cesarean section is, next to the long abandoned accouchement force, the method of treatment attended by the worst results. Yet one discovers that in most of the accepted routines some form of interference is permitted after so many hours or days of conservative treatment if improvement is not noted or the patient grows worse, and in studying many series of eclamptics treated conservatively on occasion the method of interference used appears to be cesarean section, so that we must conclude that it has a place rarely at least

in the treatment of eclampsia also after failure of conservative treatment. Latest figures, quoting Plass again, show that of eighty-four cesarean sections done for eclampsia in Iowa in 1930-1932, sixteen died a mortality rate of 19 per cent. If we compare this maternal mortality of eclampsia treated by cesarean section all over one state, which implies in some instances at least a lack of detailed care with the figures given earlier in this essay from an individual series treated in a variety of ways but practically all "conservative" we find that these cases treated by section give equally good results as the "under observation" group and twice as good results as the "emergency group." No fair conclusion can be drawn from these comparative statistics for a variety of reasons. The purpose of stressing them here is to emphasize that *method of treatment and method of delivery in eclampsia* are two, on the whole separate propositions though they sometimes interlock. The question of *method of delivery* resolves itself into adding the least possible insult to an already heavily damaged body. From a practical point of view no delivery at all or normal delivery when possible does the least mischief. How much more eclampsia a given patient will take and live and how a given doctor views this aspect of the question is an individual matter and no routine can be laid down that meets the requirements of all cases. This is justifiable criticism of all "routine conservative treatment." Constant observation, treatment including rest, and individualized action depending on the results of these will give the best results in eclampsia.

Among the untold number of remedies for and theoretical treatments of eclampsia, two deserve special mention. It has been shown that a relatively small proportion of eclamptic deaths result from cerebral hemorrhage perhaps 10 per cent to 15 per cent. Such deaths are apt to occur in elderly women, probably with a hypertension background. The rest die of or with, edema of the lungs or brain or both. The typical moribund eclamptic is clinically a cyanotic woman with wet lungs and running fluid from the mouth—the head lowered for drainage. Teel, Reid, and Hertig have shown that a few preeclamptics exhibit acute left ventricular failure, seemingly the result of the prolonged hypertension of the preeclampsia and not associated either with chronic nephritis or chronic heart disease, and in one instance death resulted in the attack. It seems likely that the wet lung moribund eclamptic is in the same state for the same reason. From these findings of cerebral edema and edema of the lungs it may be laid down as a sound principle that any treatment which may increase edema is unsound. Hence the theory of balanced fluids in the eclamptic state deserves special consideration. Since it is known that the damaged

kidney will put out only what fluids its condition allows, more fluids than this amount taken in must increase edema. If it is true on the above reasoning that increased edema is bad then it may be reasoned that any agent which tends to reduce edema, especially cerebral edema probably the cause of the convulsions, is good. This brings us logically to the intravenous and intramuscular use of magnesium sulphate in eclampsia a phase of the subject neglected in this locality.

Schwaiz and Dorsett of St. Louis (*South M J* 23 288, 1930) report 186 cases of eclampsia treated basically and conservatively with intramuscular or intravenous magnesium sulphate with a maternal mortality of 7 per cent. Rucker* of Richmond (1931) reported 109 personal cases of eclampsia treated with intravenous magnesium sulphate (20 cc of a 10 per cent solution repeated p r n for convulsions or impending convulsions) with a maternal mortality of 5.5 per cent. His previous mortality had ranged from 31.6 per cent under active obstetrical treatment to 25.9 per cent under other conservative treatment, i.e., morphine, venesection, gastric lavage, and colonic irrigation. He says of his 109 cases "In only two cases was I unable to stop convulsions." And further to show that his mortality is not a corrected one "Of the six deaths that occurred in the 109 cases of the ultraconservative group, two were not treated ultraconservatively, two died of infections after the eclampsia had subsided and only two were truly eclamptic deaths treated in the manner described." Lazard of Los Angeles and McCord of Atlanta report similar, good results by this treatment. Such results, especially Rucker's comparative ones in his own hands, are highly suggestive.

In Conclusion We have indicated our belief in emptying the uterus prior to convulsions when possible in the eclamptic state. We have indicated that if the patient has passed the convulsion phase sharp individualization in *method of delivery* and *time of delivery* is necessary and the conviction that, on necropsy and statistical grounds, an extended trial of intravenous or intramuscular magnesium sulphate treatment should be made hereabouts, and that balanced fluids constitute an additional important feature of treatment.

Each patient threatened with eclampsia should be hospitalized and given the benefit of obstetrical consultation.

*Rucker's last figures 1934 show less than 5 per cent mortality in 1-3 cases. Digitalis for the prevention of pulmonary edema and venesection if it has occurred are added to the MgSO₄ treatment.

AIDS TO THE COMMITTEE OF ARRANGEMENTS

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

Dr. Scott W. Mooring of Gloucester, Dr. Albert Parkhurst of Beverly, and Dr. Nathaniel

Breed of Lynn, have recently been appointed from the Essex South District to assist the Committee of Arrangements for the Annual Meeting of the Massachusetts Medical Society at Springfield in June.

HAMPSHIRE DISTRICT MEDICAL SOCIETY

Dr. Lawrence N. Duigin of Amherst, Dr. Thomas F. Conden of Northampton and Dr. Stephen Brown of Northampton, have recently been appointed from the Hampshire District to assist the Committee of Arrangements for the Annual Meeting of the Massachusetts Medical Society at Springfield in June.

FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY

HAVE you paid your annual dues?

Remember that if you are delinquent your *Journal* will not be mailed to you. If you wish to have your files intact, please attend to this obligation.

MASSACHUSETTS LEGISLATIVE NOTES

House Bill 59 which defines the words "stillborn child" has been enacted.

House Bill 574 which was designed to provide that hospitals receiving public support should be required to accord equal rights of admission to patients of all duly registered physicians has been referred to the next annual session.

MISCELLANY

CHANGES IN SEVERAL BOARDS OF STATE INSTITUTIONS

According to current reports, His Excellency, Governor Curley, has nominated for the position formerly held by Frank B. Hall of Worcester, as Trustee of the Grafton State Hospital, Miss Martha Ducey of Shrewsbury.

Other nominations are the following: Monroe Kaplan of Boston to succeed Mrs. Esther M. Andrews of Brookline as a Trustee of the Boston Psychopathic Hospital; Michael McGrath of Salem to succeed Robert H. Sawyer of Haverhill; Mrs. Catherine Sullivan of Canton to succeed Mrs. G. S. Sutherland of Boston as Trustee of the Taunton State Hospital; Robert Portle of Worcester to succeed Howard W. Cowee of Worcester, Trustee of the Worcester State Hospital; John H. Craig of Natick to succeed Walter Channing of Dover as Trustee of the Medfield State Hospital; and William Buiman of Brockton to succeed Horace A. Keith of Brockton as Trustee of the Foxboro State Hospital.

Appointments as Trustees of the Massachusetts General Hospital Miss Betty Dumaine Henry V Morgan James H. Buelway and Dr Joseph Sanborn.

Reappointments were Charles C. Cain of Taunton as Trustee of the Taunton State Hospital and Charles F. Riordan of Sharon as Director of the State Division of Livestock Disease Control.

AN ADDRESS BY DR. RUSHMORE

In response to an invitation by the Law Society of Massachusetts Dr. Stephen Rushmore delivered an address before that body at the Boston City Club February 25, 1936.

A MEETING OF MEMBERS OF THE LEGISLATURE WITH PHYSICIANS

Worcester physicians entertained members of the Massachusetts Legislature from Worcester and vicinity Friday February 21 at the Worcester City Club. The object of this meeting was the discussion of bills presented to the Legislature and which have a bearing on medicine and especially on public health.

After enjoying a bountiful dinner the assembly was called to order by Dr. W. F. Lynch, President of the Worcester District Medical Society who after welcoming the guests introduced Dr. A. W. Marsh of Worcester and a member of the Legislative Committee of the State Society as master of ceremonies.

Dr. Marsh explained that this meeting was accorded in precedent on occasion for presenting to certain leaders in the State Legislature the opinion of Worcester physicians respecting those bills before the Legislature which bear on medical problems.

Several doctors after being introduced by Dr. Marsh submitted analyses of some of the more important bills especially those relating to hospitals various forms of medical practice and particularly House 34 introduced by the Board of Registration in Medicine.

Dr. Morgan, President of the State Medical Society closed the discussion with a spirited appeal for the recognition of the importance of scientific medicine in dealing with the ill of the people and urged the protection of the citizenry against incompetent practitioners. In a supplemental admonition he emphasized the importance of an approved education for all physicians.

This meeting seemed to interest the members of the Legislature and is a commendable effort to secure cooperation.

AFFAIRS IN CONNECTICUT

DR. C. C. BURLINGAME SPEAKS OF WITHDRAWING THE VEIL OF MYSTERY THAT SURROUNDS THE MENTALLY ILL.

Dr. C. Charles Burlingame, physician-in-chief of the Neuro-Psychiatric Institute and Hospital of the Hartford Retreat, addressed two large audiences in

Hartford Conn. on January 31, 1936. His subject was treated in a most interesting manner. Concerning so-called mercy killing of the incurably diseased Dr. Burlingame said:

"The helpless monstrosity might not have been deprived of anything worthwhile in a mercy killing although even this is open to question. The sufferer from an incurable disease may have appeared to benefit by a mercy killing although this is open to discussion. But one thing is certain: That man has not sufficiently enlightened his sadistic tendencies to permit mercy killings without grave dangers to society as a whole suffering from a release of man's imperfectly suppressed sadism.

The speaker pointed out that the first step in prevention of mental illness is a knowledge of the nature of the disease and its causes. He traced the etiology of some mental illnesses to the stresses and strains placed on the human mind by the civilizing process in which certain destructive tendencies natural in man had to be curbed as a natural development of society. He cited war as an example of how instinctive destructive tendencies barely covered by the thin veneer of civilization, can be brought suddenly to the surface.

We need to think back no farther than our last war to see how quickly we brush aside the 'Thou shalt not kill' that we were brought up to regard as the greatest of the Ten Commandments and under the pressure of military training we have seen how easy it is to release sadistic tendencies and have millions of men accept with aplomb the job of killing.

May I here interpolate that wars will not cease until there is a change in the brain of the human being. Peace pacts, leagues of nations and balances of powers will not prevent the periodic release of man's sadistic tendencies until the individual man has developed much further. Wars will not disappear until the human brain makes a further development and finds a substitute for war.

Dr. Burlingame drew attention to the slight distinction which he said separates the normal from the abnormal in the following illustrations:

It is only a little step from a Dr. Samuel Johnson who felt obliged to touch every passing lamp post to the mentally ill person who must revolve seven times before sitting down.

It is only a step from the irate golfer who smashes his club in anger and damns his club and the hall to the mentally ill person who attributes a definite personality to the radio or to the chair in his room.

It is only a step from the smut hunting censor who sees dirt in everything to the mentally ill person who continually bathes himself to the exclusion of any productive activity in order that he may 'purify himself.'

It is only a step from the ruthless dictator who wraps himself in a cloak of apostolic fervor and

thus makes his dream come true, to the hospital patient who in his manic drive develops delusions of personal grandeur to the point where he would readily undertake a reorganization of any portion of society with the assurance that the solution of all the difficulties of mankind lay in his hand"

Pointing out the prevalence of mental illness, Dr Burlingame stated that a patient was admitted to a hospital for mental illness somewhere in the United States every four minutes of the day and night. At the regular rate of incidence, he said, out of approximately 338,000 children now in the grammar and high schools in Connecticut, 15,000 could be expected to be patients in hospitals for mental diseases some time during their lives.

Despite the magnitude of the problem, Dr Burlingame expressed the belief that mental disease need not be the great calamity that many people regard it. He said it is no longer considered "the great destroyer we once thought it was" and "that along with other physical illness, it is in large measure preventable and fortunately curable to a very large degree." He decried the defeatist attitude of blaming everything on heredity as the cause of mental disease and said that other factors such as "mal education and environment play an active part." Among a large group of mentally ill, he said, "Mental illness is merely a natural reaction to mal education and faulty training of the emotions."

He pointed out that forms of mental illness due to glandular disturbances at certain periods in life are similar to mental disturbances which accompany purely physical disorders such as the delirium of typhoid fever, and that frequently, when the physical disease is cured, the mental symptoms disappear.

Dr Burlingame emphasized the statement that almost every trait found in the mentally ill is an exaggeration of traits found in the community. "It is not difficult to understand the mentally ill person," he said. "He is as we are, only just a little more baffled by the world, just a little less able to adapt himself to it." He cited several historical cases of political and military leaders of the past, who, according to present-day knowledge, "had personalities which might be considered at least psychopathic."

The speaker advocated a more rational public attitude toward mental illness, with an increased knowledge of the necessity of preventing it by proper training, "spiritual education, emotional education, education of the man as a unit to the end that he is fitted to survive happily in his ever-changing environment."

He warned, in his conclusion, against an effort to protect children against the world, saying that too much protection was harmful.

"We must realize that the prolongation of the protected environment for the child and safeguarding him from the realities of life is part of his mis-education which may cause him to be among the 15,000 of today's children in Connecticut who will enter mental hospitals."

— ST FRANCIS HOSPITAL, HARTFORD, CONNECTICUT

At the annual meeting of St. Francis Hospital, Hartford, Conn., held on January 29, 1936, Dr James F. Lynch was elected president of the Staff. Dr. John F. Dowling, president since 1916, resigned because of ill health. Dr. Lynch is a graduate of the College of Physicians and Surgeons, Baltimore, Md. Except for about one year while in the World War he has been connected with St. Francis Hospital since 1913.

Other staff promotions and new appointments are as follows: Dr. D. Dillon Reidy, chief of the urological service; Dr. Louis P. James, chief obstetrician; Dr. Henry Katz, from assistant to attending otolaryngologist and ophthalmologist; Dr. Joseph J. Connor and Dr. Edward A. Dignam, assistant otolaryngologists and ophthalmologists; Dr. Terence F. McNulty, assistant obstetrician; Dr. John T. Winters and Dr. Christopher J. McCormack, assistant surgeons; and Dr. R. W. Whitcomb, assistant oral surgeon.

RECENT DEATHS

CLAPP—FRANK HORACE CLAPP, M.D., of North Grafton, Massachusetts, died at his home February 26, 1936. He was born in 1861. After graduating from the University of Vermont, he studied at the University of Vermont College of Medicine and graduated in 1888.

Before coming to Massachusetts, he practiced among the families of lumber camps, and later attended postgraduate clinics in New York City. Dr. Clapp was a fellow of the Massachusetts Medical Society, having joined in 1892, and also of the American Medical Association. He formerly served as President of the Worcester District Medical Society. He had served on the School Committee and the Board of Health of his town for several years and was active in many civic enterprises. Surviving Dr. Clapp are his widow, Mrs. Maud (Bailey) Clapp, a son, Dr. William B. Clapp of North Grafton, a daughter, Mrs. Florence Sanford, and a grand daughter, Barbara Sanford.

CHASE—AUGUSTUS LUCIUS CHASE, M.D., of Randolph, Massachusetts, died at his home February 29, 1936.

Dr. Chase was born in 1849 and graduated in medicine from the Eclectic Medical College, Cincinnati, in 1872. His prominence led to his appointment as one of the original members of the Board of Registration in Medicine in 1894, serving in this capacity continuously for twenty-seven years. For many years Dr. Chase served on the Brockton Pension Examining Board and was interested throughout his long life in various civic activities in Randolph.

Surviving Dr. Chase are two sons, Dr. Gilman L. Chase of Clinton, Massachusetts, Hon. Judge Herbert Chase of Cambridge, and a daughter, Mrs. Ella Cottle of Bristol, Connecticut.

DELAYED NOTICE*

MASSÉ—JOHN BAPTISTE MASSÉ, M.D., of 98 Bradford Street, Lawrence Massachusetts died suddenly October 15 1935 Dr Massé was born in Montreal Canada, in 1878 and came to Lawrence with his parents early in life He returned to Montreal to enter the University of Montreal Faculty of Medicine and graduated therefrom in 1902 and soon afterward opened an office in Lawrence for the practice of medicine In this field he was very successful and popular

He joined the Massachusetts Medical Society in 1907 and was a member of Lawrence Lodge 05 B P O E

Dr Massé is survived by ten nieces and nephews all living in Canada except Emil Massé of Biddeford, Maine. Several cousins are residents of Lawrence

Recently received.

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P M on Thursday March 12 in the Amphitheatre of the Peter Bent Brigham Hospital Dr Samuel A Levine Senior Associate in Medicine, Peter Bent Brigham Hospital, will give a medical clinic. To it are cordially invited practitioners and medical students

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12 staff rounds will be conducted.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY

PROGRAM FOR THE POSTGRADUATE INSTITUTE

Fifty four of the prominent medical educators in a city noted for its medical education—Philadelphia—constitute the faculty of the Philadelphia County Medical Society's Postgraduate Institute to be held April 20 to 24 in the Bellevue-Stratford Hotel, according to the complete program just issued*

Considerable interest has been expressed in this undertaking which the county society hopes to make an annual event and many physicians already have sent in their registrations. Notices have been sent to doctors of the nearby states and a large attendance is expected.

Dr Frank H. Lahey will deliver the J Chalmers DuCosta Foundation oration at the Philadelphia County Medical Society's meeting on the evening of April 22.

The Institute's general subject will be cardiovascular and renal diseases which the essayists will discuss from many angles. One approach will be prevention, to which little attention was paid by doctors of the older schools. This is recognized as a very practical mode of attack today

BOSTON UNIVERSITY SCHOOL OF MEDICINE SURGICAL CLINIC AT THE BOSTON CITY HOSPITAL

Friday, March 6 121 Thorndike amphitheatre
Dr Frank H. Lahey will talk on "Thyroid Disease illustrated by lantern slides
Physicians and medical students are invited.

NOTICE

Reprints of the article by Dr Francis T Hunter under the title of Hutchinson-Boeck's Disease (Generalized Sarcoidosis") will reproduce the illustrations more clearly than they appeared on pages 350 and 351 in the Journal of February 20

LAWRENCE CANCER CLINIC

Established April 17 1928

Lawrence Mass., March 2 1936

To the Physicians of the North Half of Essex County
Dear Doctor

The regular Lawrence Cancer Clinic to be held at Lawrence General Hospital One Garden Street, Lawrence, upon Tuesday March 17 at 10 00 A.M. will be a Demonstration Clinic with Channing C Simmons, M.D. of Boston, Associate in Surgery in the Graduate Courses in Medicine at Harvard University Medical School Surgeon-in-Chief to Collis P Huntington Memorial Hospital member of the Cancer Commission of Harvard University Boston and Visiting Surgeon to the Massachusetts General Hospital present as consultant. You are invited to accompany any of your patients whom you desire shall have this service or to send them with a note and a report will be returned to you The service is gratis Your attendance at the Clinic is always welcome.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society

Committee

ROY V BAKETZ, M.D.
CHAS. J. BURGESS, M.D.
FRED D McALLISTER, M.D.
JOHN J McARDLE, M.D.

REPORTS AND NOTICES OF MEETINGS

THE MASSACHUSETTS CENTRAL HEALTH COUNCIL

At the recent annual meeting of the Massachusetts Central Health Council the following designated officers were elected Miss Sophie Nelson R.N., of the John Hancock Mutual Life Insurance Company President Dr Gaylord W Anderson of the State Department of Public Health, Vice-President and

Arthur J Strawson of the Massachusetts Tuberculosis League Secretary Treasurer

WILLIAM OSLER HONORARY SOCIETY

A meeting of the William Osler Society was held February 13, 1936, at the Boston City Hospital. This is the honor medical society at the Tufts College Medical School, the membership of which is composed of highest ranking third and fourth year students. The meeting was arranged and conducted by graduate members Carl M Binnig, M D, Albert E Sloane, M D, Harry H Brenner, M D, and William Fain, M D.

From the class of 1936 the following students were elected to membership

Joseph A Reynolds, Sawyer Foster, Paul J Catinella, Benjamin Stein, Max Stein, Morris Botvin, Stanley W Machaj, Frank K Duffy, Norman E Peatfield, Mildred Adell, Jacob Mezer, Max Goldman and Israel Zeitzeiman

Formal induction of the new members will take place at the Hotel Lenox, April 14, 1936

THE ARLINGTON DOCTORS' CLUB

The regular meeting of the Arlington Doctors' Club will be held at the Nurses' Home of the Symmes Arlington Hospital on Tuesday evening, March 10, 1936, at 8 30 P M.

The speaker will be Dr Frank H. Lahey, director of the Lahey Clinic. His subject will be Diseases of the Thyroid and Parathyroids."

The talk will be illustrated with lantern slides.

There will be a general discussion.

The members of the Somerville Doctors Club have been invited to attend.

All physicians are welcome.

FRANK H GERRY, M D, *President*,

SIDNEY M SIMMONS, M D, *Secretary*

WILLIAM HARVEY SOCIETY

The next meeting of the William Harvey Society will be held Friday, March 13, in the Auditorium of the Beth Israel Hospital, Boston, at 8 00 P M.

PROGRAM

Speaker Dr Alexander Lambert, formerly Professor of Clinical Medicine, Cornell University Medical School.

Subject Therapeutics of Drug Habits.

Chairman Dr Harry Limenthal, Clinical Professor of Medicine, Tufts College Medical School.

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the office of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday March 17, 1936, at 12 noon. The speaker will be Frank H Lahey, M D, Harvard University Medical School 1904, F A C S, Director, Lahey Clinic, Surgeon in Chief, New England Baptist Hospital, Surgeon, New England Deaconess

Hospital. His subject will be "Influence of Thyroid Disease in General Practice." All physicians are cordially invited to attend. Luncheon will be served.

AN ADDRESS BY DR KENDALL EMERSON

On April 8 at Hotel Kimball, Springfield, Dr Kendall Emerson, Managing Director of the National Tuberculosis Association, New York, will address a joint annual meeting of the Massachusetts Tuberculosis League and the Hampden County Tuberculosis and Health Association. A program in the afternoon and the two board meetings will precede the dinner meeting.

GREATER BOSTON BIKUR CHOLIM HOSPITAL

Greater Boston Bikur Cholim Hospital medical meeting Wednesday evening, March 18, at 8 30 o'clock, at the Nurses' Home, 45 Townsend Street, Roxbury. Speaker Dr Herman L Blumgart. Subject Treatment of Angina Pectoris. The profession is invited.

HENRY BAKER, M D, *Secretary*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, March 10, at 8 15 P M.

PROGRAM

Presentation of Cases

Down the Lymphatics with Camera and Cannula. By Dr John Homans.

Medical students and physicians are cordially invited to attend.

MARSHALL N FULTON, M D, *Secretary*

BOOK REVIEWS

An Introduction to Public Health Harry S Mustard 250 pp New York The Macmillan Company \$2 50

This book is the fruit, both of practical experience with the actual problems involved and of teaching public health to students, graduate and undergraduate, and to nurses. In it the general principles of preventive medicine, as they may be practically applied by society to the prevention of disease, are treated in perspicuous fashion and with a nice regard for relative values. The style is pungent and lucid, although the author may be mildly criticized for the use of too many "et ceteras." The subjects treated are as follows: The background of public health, vital statistics, organization and administration of public health work, the acute communicable disease, tuberculosis as a public health problem, the venereal diseases, sanitation, personal hygiene, the hygiene of infancy and childhood, school health service and noncommunicable diseases. This is not only an excellent textbook for the student, but because of its clear exposition, could be read and studied to great advantage by the intelligent citizen.

Complete Handbook on State Medicine J Weston Walch 158 pp Portland Debaters Information Bureau \$2 50

This is a compilation of articles and opinions relating to problems incident to medical care for the people of the United States and is especially designed for study by those who may use the material in debates.

The essential arguments pro and con relating to the costs of medical care and the suggestions of interested individuals and groups as to methods designed to meet the needs of the people are set forth in this publication. Explanations of the various forms of "health insurance", state, socialized, public and industrial medicine are set forth.

Although this book is designed to make available

information relating to the economic problems of dealing with illness, there is a great deal of information between the covers which will interest economists, sociologists, and physicians.

Groups interested in carrying on debates relating to these questions will find useful material in the book.

John Whitridge Williams Academic Aspects and Bibliography J Morris Siemons 109 pp Baltimore The Johns Hopkins Press \$1 50

Dr Siemons has given us a delightful account of the life and accomplishments of an outstanding man in American medicine. An investigator, a teacher, a writer, Dr Williams stands preëminent among the American physicians of our time, and we are grateful to Dr Siemons for giving us such a stimulating account of his life.

The Theory and Practice of Anaesthesia M D Nosworthy 223 pp London Hutchinson Scientific 12/6 net

It is a pleasure to find a textbook of anesthesia that is modern in point of view and up-to-date in subject matter. Such recent additions to the field as cyclopropane, divinyl ether (vinethene), nembutal, evipal, and the carbon dioxide absorption method are well, though briefly, discussed. The chapters on premedication, nitrous oxide, carbon dioxide, acidosis, and difficulties in general anesthesia are of outstanding worth. Other subjects that are well treated are ether, chloroform, the endotracheal method, the mode of action of general anesthetics, and their aftereffects. Ethyl chloride, shock, and the stages and signs of general anesthesia are covered satisfactorily. The chapter on choice of anesthetics unfortunately rather slightspinal anesthesia as well as the newer and less frequently used drugs and methods. The section on spinal anesthesia is a distinct disappointment in that it advises neglect of blood pressure, and does not deal with the two drugs that are most commonly used in this country, namely, procain (novocain, neocain) and pontocain (pantocain). The book lacks both a chapter on regional anesthesia and a description of any gas machine commonly used in this country.

The author shows a wide and thorough knowledge of the field, and in place of the prejudices so often evident in writings on medical specialties, exhibits well balanced judgment. The book is brief, the style direct, and the pages are filled with innumerable minor helpful bits of advice. It is the only book on general anesthesia known to the reviewer that he can warmly recommend as an up-to-date, brief, practical course of instruction for medical students as well as for those physicians who only occasionally administer anesthetics. For those who wish to specialize in anesthesia it is recommended as giving a good foundation in practical work which would serve as a starting point for further studies.

NEW ENGLAND SURGICAL SOCIETY

MALIGNANCY OF THE BREAST*

BY H. C. FARVIS, M.D.†

I HAVE nothing especially new or startling to present to this Society on the question of mammary malignancy. I will present some essential facts on the general question and show some of our methods at the Hartford Hospital and also present some facts that have been brought out by our Tumor Group.

It is an unquestionable fact that in the diagnosis and treatment of cancer of the breast the same progress has not been made as in the other branches of surgery. There is no statistical proof that cancer of the breast is recognized earlier or that the results of radical operation are better than they were fifteen years ago at which time this particular study began.

There are many factors which are to blame for this deplorable state of affairs. Many women defer going to a doctor because they have a deep-rooted aversion to a breast examination; others, a natural horror of such a mutilating operation as a breast amputation. Many believe that a tumor of the breast which is painless cannot be of serious moment while still others fear to hear the truth.

The doctors who first see the cases are under a grave responsibility. In many instances medical advice is sought early, but in the absence of typical signs or symptoms of carcinoma or because the patient is considered too young for malignant disease she is either kept under observation until the diagnosis of cancer is clinically beyond doubt, or is dismissed with the assurance that there is nothing to worry about. Both of these attitudes are unexcusable. Yet once the case has come to consultation her doctor must take the responsibility for seeing that a definite diagnosis is made without delay. Thus, the ultimate prognosis rests largely in his hands.

During the last fifteen years there have been a total of over 1,000 admissions for breast cancer on 791 different patients of which number 517 represent primary admissions. In our service about 80 per cent of the delay was due to the patient. Ignorance and carelessness on the part of the patients were definite factors but

the greatest factor was fear—fear that it was cancer—and nothing could be done to help them and fear of operation and mutilation. In the near future we hope to have some definite statistics on the life expectancy of patients with cardiovascular renal disease entering the Hartford Hospital and I am led to believe that the longevity of these cases will not be so good as the mammary cancer ones. If this is true I think propaganda stating this fact will help to allay this fear that cancer is a hopeless disease.

For examination patients stripped to the waist should be examined lying flat on their backs and I believe each examiner must work out details which give him the best results. The patient, not infrequently, can localize a lesion which the physician fails to find because she is familiar with the feel of her breasts and very promptly detects any change in their structure and for this reason it is a good thing for women to palpate their own breasts at rather frequent intervals. Finally transillumination may be done although I have no real confidence in this method. A positive diagnosis of the early lesion can be made only by a biopsy.

The question of differential diagnosis will concern us for a few moments only. I would like to reiterate that the only way to make a differential diagnosis is to explore the breast and to explore it even if only on suspicion. Fisure of the nipple or erosion which is associated with a thickened duct extending into the breast, suggests the early Paget lesion. A bloody discharge from the nipple is generally indication of ductal papilloma which in 50 per cent of cases is associated with secondary malignant growth. All tumors, or even suspicion of tumors should be explored. The patient should be prepared for immediate radical operation should the frozen section from the tumor prove to be malignant.

The male breast is subject to all the different types of tumor formation that affect the female breast but the incidence of tumor in the male breast is insignificant as compared with the frequency of its occurrence in that of the female. There are logical reasons for believing that the undeveloped state of the male breast its lack of constant mobility and its consequent

*Read at the Annual Meeting of the New England Surgical Society at Manchester, New Hampshire, Sept. 26, 1935.

†Farvis, H. C.—Senior Surgeon, Hartford Hospital. For title and address of author see "This Week's Issue" page 544.

lack of exposure to the traumatism of movement may partly account for this difference. From a review of all data, it appears that Williams' figure represents the incidence of all mammary tumors as being 1 per cent in the male. In our service of 650 malignant breast tumors, there were four males or 6+ per cent.

Sarcoma is a much rarer condition. In our service it comprised less than 1 per cent and consequently because of this small number, we are unable to draw any definite conclusion.

TREATMENT

We have had no experience with the injection of colloidal lead as advocated by Blair Bell, or colloidal lead selenide as introduced by Todd.

Our cases have been treated as follows: (1) Surgical method alone; (2) By radiation alone; (3) A combination of both methods. I believe the injection methods are, for the most part, in an experimental stage. We have employed the radiation method alone in a few cases, but these cases have been so treated within the last few years, and they will not be discussed here because this paper considers only those cases operated in the last few years, with the results. We will discuss, therefore, only those cases treated entirely by surgery alone, or by surgery and radiation. We have given a few preoperative external radiations for mammary carcinoma, but not to enough cases to warrant any conclusion, but I personally feel that most carcinomata of the breast are radioresistant, so under these circumstances a preliminary application of external radiation can be regarded as a waste of valuable time in delaying the operation.

The next question to determine was what cases were inoperable. I believe a breast malignancy is inoperable: (1) When it is attached to the ribs or sternum; (2) When the supraclavicular lymphatic glands are invaded; (3) When the axillary lymphatic glands are fixed and confluent; (4) When it occurs in the fulminating and acute forms; (5) Cancer en cuirasse; (6) In the presence of distant metastases in lungs, pleura, abdominal and pelvic viscera and bones; (7) When the general condition does not justify a severe surgical operation. Except when one or more of the above condi-

tions were present all the carcinomata were operated upon in this series, even when the glands extended high up in the axilla, because, as stated before, we had nothing else to offer them except surgery and radiation. There were twelve deaths in 300 operative cases, giving an operative mortality of 4 per cent.

Wound infection	3
Pulmonary emboli	3
Pneumonia	4
Cardiac	1
Shock	1

During the period under discussion there were treated 320 cases. Two hundred and sixty-six or 80 per cent were operable. Fifty-four or 20 per cent were inoperable. The follow-up in the inoperable cases was 100 per cent and 100 per cent dead in five years. In the operable group 219 cases or 82.5 per cent follow-up, of these seventy or 32 per cent living without cancer for five years, eighteen or 8.3 per cent living with cancer for five years, 117 cases or 53.4 per cent dead with cancer in five years, fourteen cases or 6.3 per cent dead from other causes. So from our operable group at the end of five years 40 per cent are alive and 60 per cent are dead. The length of time a patient will be free from cancer depends, first, upon the type of malignancy and, secondly, on early recognition and adequate treatment of the disease.

Under the second heading we have staged our cases as follows:

- Stage I — Cancer limited to breast
- Stage II — Early and limited axillary metastases
- Stage III — Extensive axillary metastases—borderline operability
- Stage ? — Indeterminate from data available

In the group where there is a greater mortality the follow-up is better, so probably there are many cases in Group I free from disease, although of course they cannot be so counted.

Under the first heading we have a very interesting study—that is, determining by cytological examination how long each individual patient, everything else being equal, will be free from disease.

Forty years ago von Hansemann in his mon-

ograph first presented the idea that a scale might be drawn up to represent the degree to which the morphology of a tumor departs from that of the mother cells from which it arises

Greenough's 1925 study of series of cases from the records of the Massachusetts General Hospital was the first real attempt to do this grading in this country. Later workers were Patey and Scarff, Ewing, MacCarty and Haagensen. On the other hand a few American pathologists, notably Reiman, have reached the conclusion that this histological study of breast cancer has little or no prognostic value.

The pathologist who does the grading at the Hartford Hospital has followed more or less closely Haagensen's suggestions. He has made three grades, the exact details of which grading I will not bore you with at this time except to say that in looking over previous slides the slides must be in fairly good condition, and that out of our series of breast cancer, we were able to follow only 193 cases, which was 67 per cent of our entire group.

There was some difficulty during the period of 1918 and 1919, or the so-called war period where the records of cases were not so well followed and the sections not so good.

Type of Case	Number of Cases	% of Cases Living 5 Yrs	Number of Cases Living 5 Yrs
Grade I with metastases	8	63%	5
Grade I without metastases	23	95%	23
Grade II with metastases	104	33%	35

Grade II without metastases	42	62%	28
Grade III with metastases	8	00%	0
Grade III without metastases	8	60%	5

From this chart there are several conclusions one might be able to draw

1 If a patient has a Grade I carcinoma of the breast she has over 90 per cent chances of being alive at the end of five years, while those cases having a Grade III carcinoma are practically all dead at the end of five years.

2 The cases in between these two extremes vary accordingly. It is interesting to note that Grade I cases, even with metastases, have just as good a chance for a five-year survival as Grades II or III when the carcinoma is confined to the breast.

3 It is also a very interesting observation we have made that the more cases of breast tumor that are explored and found to be benign, the greater the percentage of carcinoma patients examined without metastases.

In conclusion, there are only a few things we would like to point out

1 The results of radical operation for carcinoma of the breast are not much if any, better than they were fifteen years ago.

2 The ultimate result of any one case depends upon, (1) its early recognition and, (2) upon a low grade type of malignancy.

3 The greater the number of breasts that are explored and the tumors found to be benign, the greater the percentage of malignant cases that will be found to be without metastases.

RESULTS IN MAMMARY CARCINOMA AT THE ELLIOTT HOSPITAL*

BY GEORGE C. WILKINS, M.D.† AND GEORGE F. DWINELL, M.D.†

THE purpose of this paper is to analyze as fairly as possible the results in our treatment of mammary cancer at the Elliott Hospital. This study includes all the cases admitted from September 1919 to September, 1930. During this period eighty-six cases were treated. Since 1930 fifty-one have been admitted but none of these have been considered because we believe a study of breast cancer in patients who have been operated less than five years is of little value in appraising the results of one's work.

Of the seventy-nine operations performed seventy-four radical and five palliative. Fifty-five were performed by us and the remainder

by five other surgeons on the staff. Many of the cases operated upon had a known incidence of palpable tumor for a year or more while others were fairly early.

It is certain that many patients with active extensive carcinoma and glandular involvement have been afforded a fairly long period of palliation and sometimes a cure, after being operated in a thoroughly painstaking and radical manner. Unless there are supraclavicular nodes, thoracic metastases or fixation to the chest wall, radical operation is nearly always indicated. The amount of tissue removal must be based entirely on the operative standard, and should not be reduced on account of contemplated postoperative radiation therapy.

In all but twenty early cases postoperative x-ray therapy was given and in several of the apparently more advanced cases, both preop-

*Read by D. Dwinell at the Annual Meeting of the New England Surgical Society at 31 n. hester New 11 mchire September 27 1931

†Wilkins, George C. — Surgeon, Elliott Hospital. Dwinell, George F. — Assistant Surgeon, Elliott Hospital. No records and add cases of authors see "This Week's Issue" page 544

erative and postoperative radiation therapy were utilized. It is not within the scope of this paper to discuss the merits of x-ray therapy as an adjunct to operation, but we believe every case should have postoperative radiation. The amount of x-ray therapy, as now measured in r units, has been gradually increased and if there is benefit to be derived from this adjunct we should expect better end-results in the next five or ten years.

In spite of some very encouraging reports following intensive radiation treatment of breast cancer with radium packs, deep therapy x-ray and interstitial radium, we believe surgery offers the most hopeful form of treatment in all but the definitely incurable cases and that radiation should be reserved for palliation and as an adjunct to surgery.

In practically all of the radical operations the Rodman incision was used. This incision lends itself to many modifications, the scar is usually below the axilla on the chest wall and it allows dissection from above downward without disturbing the breast and chest wall tissues until nearly the end of the operation.

Whatever form the skin incision may take, the operation itself must include a wide dissection of the skin, away from the tumor, the removal of all axillary contents, nearly all of the pectoralis major, all of the pectoralis minor and the deep fascia, including the upper anterior fascia of the rectus muscle.

Table 1 shows the results in our series after eliminating the cases that should not be included in an end-result study.

TABLE 1

Total cases admitted	86	
Radical operation	74	
Palliative (mastectomy)	5	
Radiation only	6	
Died of other causes under 5 years	6	
No operation	1	
Untraced	11	24
Cases available for end results	62	
Number cases now well (1919-1930)	22	35%
Number 5 year cures	31	50%
Number 10 year cures (op. prior to 1925)	11	18%

The involvement of lymph nodes of metastatic extension immediately lowers the probability of cure. In approximately four-fifths of our cases the axillary nodes were found involved by the pathologist. The most careful palpation of the axilla before operation may be very misleading. Negative evidence of involved nodes in the axilla is of no value.

Table 2 illustrates the serious menace to life involved in metastatic extension of cancer to the lymph nodes, and how much more favorable are the results in patients who have been operated before the beginning of lymphatic involvement.

When the diagnosis of cancer can be made immediately by inspection and palpation it also indicates a well-developed and fairly long existing tumor. Unfortunately, our present clinical methods are inadequate for making a correct early diagnosis of breast cancer.

Fixation of the skin usually means there is also axillary involvement, and in patients with large breasts the tumor usually exists for a considerable time before it can actually be palpated.

TABLE 2

Total number patients	86		
Untraced, x ray only and no operation	17		
Available for study	69		
		Living 5 Years	Living 10 Years
With metastatic nodes	54 (78%)	21 (49%)	5 (9%)
With no metastatic nodes	15 (22%)	10 (67%)	7 (47%)

We assume a universal agreement on the advisability of removing any tumor of the breast and if it is impossible to be definitely convinced as to its malignancy, the tumor should be removed, examined by the pathologist at once if possible and the wound closed, or a radical operation proceeded with. Even when it is necessary to wait twenty-four hours it apparently does not increase the danger of metastatic spread, providing a wide excision is made about the tumor and it is removed with a considerable depth of surrounding normal tissue.

We found it advisable to carry out this procedure in eleven cases, and eight of these patients have lived from five to ten years without recurrence.

Patients with inflammatory carcinoma, metastatic supraclavicular nodes or with bone metastases should be treated with deep therapy x-ray, sometimes assisted by interstitial radium. Occasionally simple mastectomy will make the patient more comfortable.

In our postoperative care we like to have the patient ambulatory as soon as possible after operation. The upper arm is held close to the side until the morning after operation.

From then on the patient is urged to use the arm as much as possible and they should be able to touch the top of the head on the third or fourth day. They sit up in bed in twenty-four hours and are usually in a chair by the third day. X-ray therapy commences as soon as the wound is healed.

Every effort should be made to induce women to examine the breasts occasionally for lumps. They should be taught that breast cancer is curable in exact relation to its early discovery and treatment. We have found in both office and clinic practice an increasing number of

women coming for breast examinations. These women, however, are from younger and better informed groups and rarely have cancer. They come as the result of educational efforts which we hope will produce better results in the future. No matter how imaginary or trivial the cause may be, these patients are commended and urged to return for examinations whenever they become alarmed.

The advisability of considering routine sterilization of breast cancer patients below the menopause age is before us now and it is reasonable to suppose that the absence of ovarian stimulation may reduce the incidence of recurrence. We intend to adopt this therapeutic measure in the future.

With increased use of transillumination of the breast the occasional use of aspiration biopsy, appropriate cases and a greater opportunity of seeing early breast cancer through education of the public there is reason for an attitude of hopeful expectancy in the end results of our breast cancer patients treated in the future.

DISCUSSION

Dr. CHARLES SIMMONS, Boston Mass. Mr President and Gentlemen—I am very glad to have heard these papers. As you all know it is a subject in which I am very much interested. I think they have covered it very fully and there is relatively little added.

Our best advice to women with a tumor of the breast is to consult a physician at once and for the physician to explore any suspicious tumor as biopsy is about the only way we can be sure of our diagnosis.

The importance of no delay is shown by a group of cases we have recently been studying in which a mean duration of the cases without axillary involvement was three months. The mean duration of the cases with axillary involvement was six months.

Roughly speaking if we see the cases early before metastases have taken place we can cure a large percentage. There are certain cases of cancer of the breast that cannot be cured by surgery, which operation is contraindicated, namely cancer in lactating breasts to young women.

The statement made by certain men that no women under forty should have a radical operation for cancer of the breast, as it is incurable by surgery, however I do not think is correct. We have had many cases of women in that decade of life with cancer of low malignancy cured by radical surgery.

In studying the groups of cases we have been impressed that the prognosis depends on two things: the extent of the disease and the degree of malignancy of the tumor. Dr. Jorvis brought this point out.

As regards the grade of malignancy to low malignancy we obtain approximately 90 per cent of 5-year cures to medium malignancy 45 to 50 per cent in high malignancy 15 to 20 per cent. We have had a few cases of high malignancy cured by surgery even some with axillary involvement. Although the degree of malignancy does not influence the treatment it gives some idea of the prognosis in a given case.

We have found that from 10 to 15 per cent of the cases living without evidence of disease at the end of five years will develop late metastases.

At the present time a great deal has been said and clinics and laboratories are working on the relation of the ovarian hormones to cystic disease and cancer of the breast. At certain clinics an artificial menopause is being induced in every woman with cancer of the breast before the menopause to destroy the ovarian hormone. This was suggested originally by Beatson in 1898 and Toot of Roonke has done some work on the subject.

All we can say at present is that it is an interesting piece of investigative work.

Another point that has caused much discussion is the value of preoperative and postoperative radiation. Several years ago at the Massachusetts General Hospital Dr. Greenough and I operated upon practically all the breast cases in order to have control. On the group one half of these cases were referred to Dr. Holmes for prophylactic radiation. The remaining cases received no radiation. Dr. Holmes chose to give preoperative radiation treatment. In comparing the five-year results of these two groups the percentage of cures was found to be the same. We are speaking of radiation as given in 1920, to 1930. We now give much higher dosage. On the other hand other investigators were using approximately the same dose at that time. All we can say is that apparently in our hands it had no effect on the prognosis and that our figures do not agree with those of certain others. At present we are not recommending it if there is a good chance of permanent cure by surgery.

Before operation all cases have x-ray films taken of the lungs, spine and pelvis and often the skull to rule out the possibility of remote metastasis. If remote metastasis is present the case should not be operated upon for the disease can be controlled as well by radiation.

The results of radiation as a palliative measure and in prolonging life are striking.

I was glad to hear Dr. Dwinell state that he allows the patient to use the arm shortly after operation. I use a scultetus bandage with the last half of the scultetus as a shoulder strap. The patient is allowed to use the arm from the first. The patients may have more serum in the wound but there are fewer stiff shoulders.

About the amount of tissue removed we take out the breast, both muscles and the contents of the axilla. If the skin is sufficiently undercut it is possible to remove all the tissue necessary and yet be able to close the wound in the majority of cases. First intention healing will not be obtained in every wound by any manner of means if sufficient tissue is removed.

PRESIDENT JOHNSON. These papers are open now for general discussion.

Dr. ERNEST M. DALAND Boston Mass. I would like to show two slides in connection with this subject and also in connection with the paper that I am going to read a little later in the afternoon.

One thing I would like to emphasize that both men have referred to is the importance of removal of muscles. Dr. Walnwright of Scranton Pennsylvania a few years ago demonstrated that the pectoral muscles should be removed for two reasons: first, that they cover the upper axilla and we cannot expose the upper axilla without taking out the muscles; not more important is the fact that the muscles may become involved in cancer. He showed a number of large slides, full sections of the breast in which he demonstrated cancer in the muscles and in front of the muscles. He pointed out that one should take out all the muscle to the insertion and

also that one should reflect the skin flap and cut the insertion without seeing the rest of the muscle, because he felt that there were nodes and nodules in front of the muscle that might be spread

(Slide 1) This is a group of one hundred untreated

SLIDE 1 Surg Gynec & Obst 44:265 1927

ed cancers of the breast A little later I am going to give you some cures on one hundred untreated cancers of the rectum

The first curve, Curve A, is a survival curve of one hundred untreated cases These patients had absolutely nothing done in the nature of operation or radiation At the end of five years we have 22 per cent living with the disease, 5 per cent at ten years, and the last two patients died at thirteen years Those patients had cancer all the way through the thirteen years This is a chart we published four or five years ago These other curves are from the Massachusetts General Hospital Curve B represents sixty six radical operations with and without x-ray, with and without axillary nodes The survival is very definitely above the other line, and we have at seven years 35 per cent well These are from onset of symptoms and not seven years postoperative They probably average about five years postoperative

The third group includes sixteen selected cases without axillary nodes, with 62 per cent alive and well at seven years There was one operative death. (Indicating) This is a case that accidentally got into the series She did have supraclavicular nodes, but not axillary nodes

There is just one further point which is that the median point in this curve is at the end of two and a half years At the end of two and a half years, half of these patients were dead and half were alive The median is a little different from the average The average figure was forty months as against thirty months, the median figure Every thing above this line is gain from operation

(Slide 2) Dr Burton Lee of the Memorial Hospital charted one hundred and thirty three primary breast cancers against this curve The only difference between his cases and mine is that his patients were a little younger than my group They average four or five years younger and, therefore, he felt that the grade of malignancy and rapidity of growth would have been greater in his series But the duration of life is exactly the same as in the group of untreated cases

The only other thing in favor of this primary radiation without operation in this group is that in many instances he healed the ulcerations, kept cancer from breaking down and, doubtless, made his patients a little more comfortable One hundred

and thirty-three cases treated by primary radiation instead of operation because they were inoperable, lived no longer than if they had been untreated

SLIDE 2

DR GEORGE C WILKINS I have very little to say because so much that can be said has already been expressed by the speakers and by the men who have discussed the papers

I wanted to bring out the point of early diagnosis by excision as being not perhaps harmless, but perfectly justifiable I think the nearer we get to early diagnosis in cancer of the breast, the more difficulty we are going to have in making an absolute diagnosis of the tumor by any of our known methods, by palpation or by any of our clinical methods, I mean

So that leaves it that the only way open is to examine the tumor microscopically, and to do that it must be removed As we said in our paper, it can be done by removing the tumor with a good margin and having it examined I do not believe it is going to be detrimental to the recovery of the patient

There is one thing we must always beware of in tumor of the breast, with a small tumor, and that is to get the idea that it is an early tumor It may be a slow growing tumor We have had several of them in which the tumor was small and the axillary nodes were larger by one or two sizes than the original tumor

In regard to sterilization in the patients under fifty or under menopause age, I do believe that it offers something in the way of improvement in the after-results for those patients The paper of Dr Dresser before the American Radium Society last spring at Atlantic City rather convinced me of the value of it. I think it is worth carrying out.

In regard to the relative values of preoperative and postoperative x ray, I believe the postoperative x-ray is the more important The objection to the preoperative x-ray with our present day methods of using the x ray is that if we give enough x ray before operation to do some real good, the operation is going to be extremely difficult and the healing very slow In the old days, when comparatively small x-ray dosage was given, one could operate afterward without any particular trouble, but with the dosage that should be given today, either before or after operation, you will find it a very difficult job to remove the breast

Also, there is so much tissue that will take up the x rays, and the deeper tissues, deeper lymphatics, which are the ones we wish to get at, are so far

beneath some of the breasts that I doubt the efficiency of it. After the breast is removed and there is nothing but skin over the ribs then the x-ray will do all the good possible.

I just want to say one more word about the value of the Rodman incision. I am very much pleased with it and I think a better chest wall better axilla and better movement of the arm result when that technique is used.

DR. JON VINCENT MEYER Boston Mass. I should like to sound a word of warning to those roentgenologists who are attempting destruction of the ovary by x-ray treatment in order to determine the value of such treatment in cancer of the breast in the woman who is still menstruating. Even though menstruation is stopped by x-ray treatment, it does not necessarily follow that the ovarian hormone is destroyed. We have had a number of patients in the hospital recently who even though menstruation had ceased still had estrin in the urine and no prolactin. If the menopause had occurred prolactin should be present and no estrin. Therefore I think that before statistics are presented on patients who have had treatment of that sort, it should be determined that the actual menopause had been brought

about. The only way at the present time that that can be done is to determine the estrin and prolactin content of the urine of each patient. Endometrial biopsy to determine the state of the endometrium should also be carried out. If it is atrophied the menopause is probably passed, but if proliferation or secretion is present the ovaries are still active.

DR. ALFRED M. ROWLEY Hartford Conn. *Mr. President*—No mention has been made of chronic mastitis the lumpy breast, which may harbor malignancy. I wish to make a plea, that these cases be carefully watched so that a true growth may not be overlooked. The public and physicians have been instructed through the teaching of those who have had much experience in breast pathology and surgery that chronic mastitis is not followed by malignancy. We have had several cases in which the two conditions were associated. I also wish to call attention to the method of examination of breast tumors in our tumor clinic. In the last few years we have allowed but one or two physicians to examine the breast tumor. If many roughly palpate a growth malignant cells may be expressed into the lymphatics.

MORPHINE AND INTESTINAL ACTIVITY*

BY FREDRICK F. YONKMAN, PH.D., JOHN M. HIEBERT, M.D., and HARRISHEN SINGH, M.D.

ANTEDATING Plant and Miller¹ morphine was held to be a "howel miller", by virtue of its supposed immobilizing effect on the intestine. But since the appearance of the excellent contribution by the Iowa investigators, ample confirmation^{2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36,37,38,39,40,41,42,43,44,45,46,47,48,49,50,51,52,53,54,55,56,57,58,59,60,61,62,63,64,65,66,67,68,69,70,71,72,73,74,75,76,77,78,79,80,81,82,83,84,85,86,87,88,89,90,91,92,93,94,95,96,97,98,99,100} has been so forthcoming as to modify our views concerning the true action of morphine and certain other opium alkaloids on intestinal activity. Instead of inhibiting the intestine by a depressant action we now have the conception that in ordinary dosage of 1/8 and 1/4 grain, morphine attains its clinical advantages through stimulation of motility and tone.

METHOD

While studying the effects of various doses of strychnine¹ on the intestine we were privileged to observe also the effects of morphine in five patients, a woman and four men, two of whom had a Mikulicz operation, one a cecostomy and two a colostomy. To obtain a graphic record of what occurred in the intestine we used the same method employed by Plant and Miller and others. Long sausage shaped, rubber balloons tied to rubber catheters were inserted into

the large and small intestines of the patients. The catheter was then connected to a water manometer in which any change in water level (at 25 cm. pressure) and hence in air volume was distributed graphically to a smoked paper on the kymograph through a modified² Brodie air bellows. All patients were given break fast, and the balloon was usually inserted with pain in no instance, at about 9:30 or 10:00 A.M. The patient was allowed to assume a comfortable position on his back in his own bed and varied slightly from this position for four six or seven hours with little discomfort. All injections of morphine sulphate were given intramuscularly after a normal record of one hour's duration or after the effect of strychnine had disappeared.

Our kymograph was so placed at the bedside that the patient saw no part of the record unless shown to him by mirror image. This was willingly done when the patient manifested interest in the proceedings. As well as could be determined these diversions left no effect by way of altering the existing record. Conversation was indulged in, but within reasonable limits and ward activities were partially excluded with screens.

RESULTS

Notes. Fig 1 represents a record taken from a man with a Mikulicz operation which allowed access to his ileum as well as ascending colon. The normal record shows his intestine to be very active. At this time he was complaining of the excessive "hurning" which accompanied the excoriation in the abdominal "scar pocket" surrounding the operation. With the hope of

*From the Department of Pharmacology Boston University School of Medicine and the Evans Memorial Hospital.

¹No attempt has been made to enumerate every investigation concerning the action of morphine on the intestine; a space excellent review is given by most author quoted in this paper.

²We are greatly indebted to Dr. H. M. Pollock, Dr. W. Christie, Dr. A. L. Lannan and Miss V. Ballou, R.N. of the Massachusetts Memorial Hospital and to Dr. W. R. Morrison, Dr. E. S. A. King, and Miss Agnes MacDonald, R.N. of the Boston City Hospital for their hearty cooperation in this investigation.

Yonkman, Fredrick F.—Associate Professor of Pharmacology Boston University School of Medicine. Hiebert, John M.—Associated with the Department of Clinical Research, Winthrop Chemical Company. Singh, Harkishen—Intern in Pathology, Massachusetts General Hospital. For records and addresses of authors see "This Week" issue, page 514.

slowing up his intestine to allow for maximum absorption and hence lessen the fluid content of the ileum as it arrived distally, atropine, in the form of tincture of belladonna, was administered for three days. Slight relief was obtained but not sufficient because of seepage of the added fluid intake required to satisfy the patient's excessive thirst. The record from the ileum, however, reveals almost complete absence of peristalsis. In this condition morphine was admin-

Fig 3 is taken from a woman with a Mikulicz operation whose ileum was not so accessible. Hence her colon only was studied. As the record demonstrates, morphine, 15 mgm (1/4 grain) in a colon not acted upon by 2 mgm (1/30 grain) of strychnine, elicits a definite increase in tone and a rather pronounced increase in rhythmic frequency. About forty-five minutes after injection the patient began to vomit with gradual return of tonus to normal.

FIG 1 Man aged fifty three Mikulicz, record of ileum February 18 1933 Time interval in minutes At 10 49 A M 8 mg of morphine intramuscularly At 12 45 dinner with brandy (30 cc) at 1 05 P M Cramps indicated by \ marks

istered in 1/8 grain dosage resulting in a definite stimulation of tone and peristalsis which persisted for one hour. This patient is of special interest since morphine activated the quiescent, atropinized bowel which fact Plant and Miller¹ first demonstrated in their unanesthetized animals. The remainder of the record shows the effect of dinner and brandy after morphine. Peristalsis, with "cramps", prevails

in the next two hours. In our series this woman was the only patient to vomit.

Fig 4 is a record taken from a man's ascending colon approached through his cecostomy. The interesting feature as regards his "normal" is the slight activity present. This was augmented appreciably by a large dose, 3 mgm (1/30 grain) strychnine for almost two hours when the man's hunger was mildly ap-

FIG 2 Man aged fifty three Mikulicz, record of colon February 15 1933 Time interval in minutes At 1 55 P M 15 mg morphine intramuscularly At 5 05 P M brandy (30 cc) Cramps indicated

Ascending Colon Fig 2 is a record of activity of the ascending colon of the patient described above. These records were not taken simultaneously, the colon was studied three days before the ileum. This tracing also shows that morphine had rather marked, stimulating effect on the colon as regards tone and peristalsis, tone persisting at 20 mm above normal three hours after morphine administration.

During this study of the ascending colon, increased activity was observed in the ileal "stump" at the site of operation. The ileum flared out trumpet-like with each wave of activity and after morphine we recorded ten to twelve waves compared with seven and eight per minute prior to morphine. We feel that these waves of activity represented rhythmic waves because of their frequency. At the same time, however, fluid seepage seemed to increase at the ileal "stump."

peased by a few crackers, the effect of which is definitely recorded. To serve as a control, thus obviating any "psychic" effect of the needle, one cc of normal saline was injected with no stimulation following. Forty-five minutes later 15 mgm (1/4 grain) of morphine produced a very gradual increase in tone with only slight, delayed effect on rhythmic and peristaltic activity. This case presents the least activation observed in our series. When compared with figs 2 and 3 one finds these particular ascending colons much less active normally than the distal colons to be described below. The suggestion comes to mind that a lessened activity might be expected with diminished function of the large bowel accompanying cecal elimination.

Fig 5 represents the record of activity of a man's distal colon approached through a colostomy. A fairly active distal colon was depressed by 2 mgm (1/30 gr) of strychnine and in this

condition morphine 15 mgm ($1/4$ gr) was administered with slight and delayed increase in tone resulting. The tone increase persisted for an hour and was accompanied by a definite in-

crease in rhythmic and peristaltic waves. Gas was passed at various times further demonstrating propulsive activity. This patient was not observed beyond the second hour following morphine. nine after which morphine $1/4$ gram produced an immediate and pronounced stimulation both of tone and rhythmic activity. Peristaltic frequency was also increased but is not so readily perceived from the record due to the marked

FIG. 3. Woman, aged forty-four, with cecal approach and record of colon June 19 1932. Time interval in minutes. At 4:16 P.M. 5 mg of strychnine intramuscularly. At 4:58 P.M. 15 mg of morphine intramuscularly. Vomiting (V) indicated.

FIG. 4. Man, aged fifty-two. Cecostomy March 2 1934. Time interval in minutes. At 11:10 P.M. 5 mg. of strychnine intramuscularly. At 3:10 P.M. 1 cc. saline intramuscularly. At 3:55 P.M. 15 mg of morphine intramuscularly.

FIG. 5. Man, aged fifty-eight. Cecostomy February 12 1934. Time interval in minutes. At 11:05 A.M. 5 mg of strychnine intramuscularly. At 1:58 P.M. 15 mg of morphine intramuscularly. Gas escape indicated.

crease in rhythmic and peristaltic waves. Gas was passed at various times further demonstrating propulsive activity. This patient was not observed beyond the second hour following morphine.

nine after which morphine $1/4$ gram produced an immediate and pronounced stimulation both of tone and rhythmic activity. Peristaltic frequency was also increased but is not so readily perceived from the record due to the marked

increase in tone and rhythmicity. For almost two hours after injection, morphine had maintained this extreme condition, following which there was a gradual return toward normal within the next hour. At the end of three hours and fifteen minutes, tone was still higher than

we observed that the drug in smaller dosage, produced an increase in tone for over an hour, a marked increase in peristaltic amplitude and frequency and a marked increase in rhythmic frequency and amplitude. After two hours the picture appeared normal. Saline was given

FIG 6 Man aged fifty five Colostomy, February 15 1934

before morphine, and peristaltic and rhythmic frequency were still augmented. This patient had been studied for seven hours before supertime terminated the observations.

Because of the pronounced activity observed in this patient with 1/4 grain of morphine we desired to learn the effect of 1/8 grain dosage. Thus three weeks later as fig 7 demonstrates,

about one half hour later to rule out "psychic" effect of the needle. The record shows no change. Then morphine, 1/4 grain, produced a picture somewhat similar to that resulting from the same dosage in the same patient as shown in fig 6. The increase in tone is marked in both, but the increase in peristaltic frequency is more evident in fig 7. After one hour the effect of

morphine was still very marked but the patient was observed no longer since supper trays attracted his attention after six hours of observation.

During all of our observations we were alert for any expressions from the patients regarding their experience of pain, general discomfort or any untoward sensation. Thus we learned from one patient that after morphine he felt a sensation of wriggling activity,—in his own words, "wormy movements." Another said he felt like passing gas. One said that he was positive he could "produce a movement" if he could only sit upright (and this despite the fact that his rectal colon was disconnected and non functioning)! Could a balloon have been inserted rectally, it might have graphically verified his contention. Some of our patients said they felt "cramps." Our interest was directed to the time of appearance of the cramplike pains. We found three variations. In some they appeared at the height of a peristaltic wave, in others they appeared at the beginning of a wave while in one patient complaint of a "mild, dull cramp" appeared after the curve showed that the balloon was filled, i. e. at the conclusion of a peristaltic wave. This cramp probably was due to distention but why it should appear at the end of a wave, rather than prior or during is of speculative interest.

DISCUSSION

All of our patients showed some form of stimulation of either ileum or colon, the result depending upon the individual patient, the area studied and the dose of morphine employed. We hope to add cases to our present group from time to time as opportunity affords. If future results are comparable with those reported here and by other investigators we see logic in the contention that morphine should be used in suspected peritonitis to prevent excessive distention provided the dosage is repeated with sufficient frequency—perhaps at three or four hour intervals as is at present advised and practised in many hospitals. Dr. Charles F. Branch of the Department of Pathology concurs in the opinion that where there is probability of a weakened intestine to perforate, increased tone under morphine might be advantageous, since distention, a factor augmenting perforation mechanically, would be obviated. Further, ulcerative margins might repair more readily when in close approximation rather than in a flaccid or distended bowel.

Postoperatively, morphine by increasing bowel tone could conceivably relieve so-called "gas pains" by preventing distention. Increased

bowel activity would promote gas passage and also allow for better absorption of gas as well as liquid. Thus, comfort received from morphine is apparently brought about by a peripheral stimulating action in the intestine as well as by a central depressant action on pain perception.

In intestinal hemorrhage, morphine would offer relief more quickly if tonus were increased than if the intestine were relaxed. If one compares the action of morphine on the intestine with the action of ergot on the uterus post partum one sees the fallacy of attempting to explain the efficacy of morphine on the basis of bowel relaxation which obviously would increase the hemorrhage. One might suspect increased activity to interfere with clotting but if sufficient dosage is employed the most prominent effect is the excessive tone increase which one also observes with ergot in the uterus.

SUMMARY

The action of morphine on the intestine was studied by the "balloon method" on seven occasions in five patients, with cecostomy, colostomy or a Mikulicz operation. In all cases, except one, some form of stimulation was soon observed in the area of intestine studied, in the exception, a delayed response followed at myoelectric depression. The beneficial effects of morphine's stimulating action on the bowel are discussed in relation to postoperative ileus, peritonitis, perforation and intestinal hemorrhage.

The meeting was called to order by the President at 12 05. The Secretary read an abstract of the records of the previous meeting. The record in full was published in *The New England Journal of Medicine*, issue of November 28, 1935. The records as published were declared approved.

The President then proceeded to read the obituaries of the Councilors who had died since the last meeting.

DR. JOHN SHEPARD MAY of Jamaica Plain with an office in Roxbury, died suddenly October 10, 1935. He was born in Augusta, Maine, in 1870, the son of John H. and Ellen F. (Guild) May. He graduated from Bowdoin College in 1893 and from the Jefferson Medical College in 1897. After receiving his medical degree, he settled in Roxbury where he practiced the remainder of his life.

He was a Fellow of the Massachusetts Medical Society and of the American Medical Association and a member of the West Roxbury Medical Association.

Dr May is survived by his widow, a sister and a brother.

DR TIMOTHY JOSEPH MURPHY of Roxbury with an office in Boston, died January 1 1936 after a short illness.

He was born in 1866. He graduated from Boston College in 1888 and received his M.D. degree from the Harvard Medical School in 1892.

Dr. Murphy was chief of staff of the Boston Sanatorium, Professor of Medicine at Tufts College Medical School, a member of the staff of St. Margaret's Hospital, and had served as President and Censor of the Norfolk District Medical Society, and at the time of his death was a member of the Council.

He was recently appointed Medical Examiner of the M. C. O. F. In addition to the Massachusetts Medical Society, Dr. Murphy was a Fellow of the American Medical Association.

He is survived by six children.

Dr. Wilhem R. Morrison, Suffolk, presented a report of the Committee of Arrangements for the Annual Meeting. It is quite apparent that much interest is being shown in the coming Annual Meeting which will be held in Springfield. (See Appendix No. 1.)

The Treasurer read his annual report showing that the finances of the Society are in excellent condition. (See Appendix No. 2.) It was voted to accept the report and the President, Dr. Monahan, complimented the Treasurer upon it. Dr. Stetson Franklin, moved that the Council record its appreciation of the excellent work done by the Treasurer. This was seconded and passed.

The Auditing Committee was not present to submit its report and the President directed the Secretary to read the report of the Certified Public Accountants, Hartshorn & Walter which indicated that the accounts had been duly checked and found correct. (See Appendix No. 3.) The Treasurer informed the President that the Auditing Committee appeared with him at the safe deposit vault on January 7, checked his securities and promised to present a report at this meeting. It was moved and seconded that the explanation of Dr. Butler together with the report of the Certified Public Accountants, be accepted as the report of the Auditing Committee. (The report of the Auditing Committee was received after the meeting and is published as Appendix No. 4.)

Dr. Blakely, Norfolk, presented the report of the Committee on Membership and Finance on changes in membership. (See Appendix No. 5.) The Council voted to accept the report and subsequently voted to adopt the recommendations contained in the report. Dr. Blakely then proceeded to present that portion of the report of his Committee dealing with finance. (See Appendix No. 6.) The President commented upon the task which confronts the Committee on Membership and Finance and called

for a vote upon the acceptance of the report. It was unanimously adopted. He next asked for action on the recommendations contained in the report and this was likewise passed without exception. The President then paid a tribute to the work of Dr. Blakely and his Committee and pointed out that this has been so well performed that with the exception of two years the Society has lived within its income. The Council passed a vote of thanks to Dr. Blakely.

The Council then moved to go into executive session to consider certain matters of a confidential nature. There was no action recommended and the Council then resumed the regular schedule of work in ordinary session.

The President announced that since the work of the Committee on Public Relations had been divided among its various subcommittees he would call upon the chairmen of these subcommittees following a short recess for luncheon (Recess from 1:10 to 1:45 P.M.).

Inasmuch as the report of the Committee on Postgraduate Instruction had been received and was quite brief it was read at this time and was accepted by vote. (See Appendix No. 7.)

Dr. Channing Frothingham, Suffolk, reported for the subcommittee on Public Health and Practitioner of the Committee on Public Relations. He stated that the subcommittee had been trying to stimulate the practitioners of the State to take a more active interest in public health problems including that of immunization. As a result, the Council had passed a series of motions at the last Annual Meeting, in which health departments and public health officials were urged to do no more immunization work than was absolutely necessary and urging the practitioners to engage in this preventive treatment. The result of these votes has been a certain amount of criticism from public health officers who interpreted the action taken as an attempt to have the work discontinued by them. It seems to the subcommittee therefore that a very definite challenge has been given to the physicians to take this phase of preventive medicine seriously or stop making complaints against public health officials for performing this most essential work. The chairmen stated that the subcommittee was asked by the Committee on Public Relations as a whole to formulate a statement which might be printed and endorsed by the Society through the Council with the understanding that such statement could be distributed to the laity by physicians without its being considered unethical. Such a statement could be handed to patients as they leave lying in hospitals and also could be issued by public health officials the whole procedure being carried on with the idea of trying to educate the public respecting the value of immunization and also to teach the public that this work should be done by the physician. In accordance with these instructions the subcom-

mittee made certain recommendations which were approved by the full Committee at its last meeting (The recommendations appear on a card) (See Appendix No 8) Dr Fiothingham went on to state that the sentence, which reads "Family physicians throughout the Commonwealth are organizing to do this and other work in preventive medicine at a price commensurate with the patient's ability to pay", has led to a certain amount of misunderstanding but is the result of the consensus of physicians in Boston, including the Norfolk District, Suffolk District and Middlesex South District, who have organized to do this work at a price commensurate with the patient's ability to pay. The report of the subcommittee was accepted by the Council and by a separate vote the recommendations of the subcommittee were adopted.

Dr Tighe, Middlesex North, reported for the subcommittee on Social Legislation and Insurance. He recounted the progress which had been made by the committee in conducting a campaign of public education throughout several districts on the evils of compulsory sickness insurance. In certain districts the work has been handled with enthusiasm while in others not much has been done. He called attention to individual addresses which had been given to lay audiences by certain members of the Society and quoted favorable comments from newspapers. He announced that there would be a radio program on Saturday, February 8, at 9 30 P M on Station WNAC of the Yankee Network. This program was planned to include a five-minute introduction by President Mongan on the aims and purposes of the Massachusetts Medical Society and the reasons why the Society is engaged in this program of public education. There would follow a fifteen-minute period of questions and answers. Dr Mongan would ask the questions and the replies would be given by Dr Tighe and Dr Begg. The last ten minutes of the program would be used by the President in summing up the arguments which had been developed in the question period. Dr Tighe reported that the subcommittee was also engaged in a study of plans, which have been suggested or which are in operation, designed to offer a means of meeting some of the difficulties in the way of making adequate medical care available. He announced that Mr Ross Garnett, the Coordinator of the Medical Economic Security Administration of Washington, D C, was to be in Boston on February 17 and 18 under the auspices of the Massachusetts Medical Society, the Massachusetts Dental Society and the Boston Hospital Council. Dr Tighe's remarks were accepted as a report of progress.

Dr Hunt, Worcester, reported for the subcommittee on the Adequacy of Medical Care. He stated that the plan in Worcester which was proposed for support by the Works Progress

Administration had been refused approval after consideration for a period of eight months. He stated that with the aid of Dr Lombard of the State Department of Public Health a questionnaire blank had been prepared for the purpose of making a test survey of people of low income in the Worcester District. This survey had included one hundred families. In addition the members of the Committee on Public Relations had undertaken to include twenty-five more families each, so that four hundred families shall have been studied when the survey is completed. He suggested that the Councilors present might assist in the survey if they would take a number of the forms and persuade the local district nursing groups to conduct a similar survey. While he would not care to commit the Society to an expense, he stated that for each family in the Worcester survey those who made the study were paid twenty-five cents for the information on each card that was turned in. He thought that with proper cooperation the survey might be extended to include one thousand families. Pending a completion of the survey the committee felt that it would be profitable to consider some of the studies which had already been made, particularly the medical service represented by the distribution of physicians, hospitals and perhaps the nursing service. His charts showed, for instance, that there is one doctor to each four hundred of the population in the eastern part of the State whereas in the western part there is only one doctor to each nine hundred of the inhabitants. It also appeared that there is one hospital bed for every two hundred and twenty-one persons in the State of Massachusetts not including those in special hospitals. The committee is attempting to gather material for an exhibit at the Annual Meeting in Springfield. He reported that the newspapers in Worcester had inquired as to the object of the study and had offered to help by stating the purposes to the public and by publishing a copy or condensation of the questionnaire so that people might fill it in and send it to the committee voluntarily. The Council voted to accept Dr Hunt's statements as a report of progress.

Dr Blaisdell, Middlesex East, reported for the subcommittee on Hospital Relations. He recalled to the Council that in June, 1933 recommendations of the Public Relations Committee had been adopted which stated that industrial cases should be hospitalized as private or semi-private cases. In March, 1935 the Supreme Court in the Zombra case rendered a decision which liberalized the interpretation of the clause in the statute which provides for a choice of physician by the patient and to that extent sustained the position of the Society. He reported that conferences with the Industrial Accident Board had not been successful in leading to an interpretation of its rules as to free

choice but it does appear that, since the Zombra decision and since the agitation by the committee the Industrial Accident Board has been more liberal in certain specific cases. In the opinion of legal counsel there should be a selection of cases which can be brought before the Supreme Court in order to clarify the situation. Dr Blaisdell's statements were accepted by the Council as a report of progress.

Dr Mongan then called for the report of the Committee on State and National Legislation which was read by the Committee's secretary, Dr Lionherger, Norfolk. (See Appendix No 9.) The report of the Committee was formally accepted by the Council. The President stated that he would like to stress the reference made in the report to the practice of individual members of the Society of introducing bills in the Legislature and then asking for the support of the Society. He stated that this was not the proper method. If a bill is worthy of support it should be referred to the Committee on State and National Legislation for study before the Society is committed to its support or its opposition. In answer to a question from the floor President Mongan stated that the Committee on State and National Legislation did not feel disposed to decide upon the question of support or opposition to the proposal made by the Board of Registration in Medicine that physicians be required to register annually. It was decided therefore, to place the matter before the Council for its consideration. He then directed the Secretary to read House Bill 35 which is entitled "An Act providing for the Annual Registration of Physicians and the Annual Publication of the List of Physicians duly registered."

Dr J B Hall, Norfolk, spoke on the previous attempt which had been made to procure similar legislation and stated that he thought that since that time there might have been some change in the opinion of the members. The speaker's opinion differed from that of several years ago although the idea was expressed that the annual registration fee might be one dollar instead of two and that this reduction might be more acceptable. He moved that the Council approve of the legislation. The motion was seconded and discussion was called for.

Dr Richard Dutton, Middlesex East, read an extract from an editorial in *The New England Journal of Medicine* for December 12 1935.

Dr Burnham Essex North, commented on the editorial quoted and emphasized the principle that there should be a published list of physicians in Massachusetts. He suggested that the Editor of the *Journal* tell the Council if in his opinion, a simple bill for registration of physicians, having the approval of this Society, would be a move in the right direction.

In response to the President's request Dr Bowers, Worcester, stated that the purpose of

the bill in his opinion was good. He thought that the objection raised here, namely, that the law now provides adequate facilities for taking care of the situation, is theoretically correct but practically faulty. The law to register physicians is an exercise of the police power of the State and it is the duty of the police officers to carry into effect laws relating to registration and to see that physicians are registered. His experience led him to believe that the police of the State have not assumed that function. He failed to find cooperation and upon several occasions had been obliged to institute proceedings in the Court in order to secure action. It was stated that in all our cities in the Commonwealth there are a certain number of people who are practicing medicine without being duly registered. Since most of these are incompetent practitioners, every licensed doctor who practices medicine ought to be registered under the provisions of the bill in order to promote the safety of the people. The size of the fee which seemed to be the stumbling block could be reduced by a modification of the stated amount. He pointed out, however, that it was necessary to have a certain amount of money available if the Board of Registration is to carry out its policies. This money would be expended in the hire of trained investigators who would operate throughout the State. It was further stated that the bill was looked upon with favor since it was an effort to improve the practice of medicine in Massachusetts.

Dr Tighe Middlesex North, pointed out that after all, as Dr Bowers had stated, enforcement is up to the police who evidently have no interest in the matter and the State Board of Registration in Medicine has no funds which it may use for the hire of investigators to discover and prosecute these illegal practitioners. He pointed out, however, that when a tax is paid to a city or state the money goes into the general fund and he saw no provision in this bill whereby the tax of two dollars would go for the use of the Board of Registration in Medicine.

A Councilor from Middlesex East stated that objection had been raised in that District to the power given to the Board in asking for such other information as they might require. He felt that there was no objection to the registration but that there was distinct objection to the powers given under the bill. On January 8 Middlesex East District Medical Society went on record as opposing House Bill 35 as now written.

Dr Burnham, Essex North replied to the member from Middlesex North and stated that while he was not absolutely certain, from reports of the Board of Registration in Medicine it would appear that the money now collected by the Board for examinations goes into its

funds and that they use it as they please and that any money left over is paid to the State. He felt that under these circumstances one would suppose that the two dollar registration fee would go into the same fund. Dr Burnham noticed that Dr Bowers disagreed with this opinion and suggested that he explain it. In the meantime he mentioned as an amendment that we go on record as approving the bill if it can be made satisfactory to the Committee on State and National Legislation.

Dr Bowers asked for the privilege of interrupting to make an explanation. This request was granted and Dr Bowers proceeded to show that the Councilor from Lawrence was misinformed about the funds of the Board of Registration in Medicine. It was explained that the Board operates under an appropriation as do all other Boards and that the earnings of the Board are turned over to the State Treasury. As a result the Board of Registration in Medicine has contributed to the funds of the State a sum considerably in excess of its expenditures. He stated that the Board had repeatedly asked for an investigator and had been consistently denied on the basis of the argument that the police departments would take care of the irregularities, but that it was the purpose of the Act to secure a sufficient number of investigators to supplement the work of the Board.

Dr Mongan stated that there is no provision in the bill that the money raised by registration shall go otherwise than into the Treasury. He ruled that the amendment proposed was so comprehensive that it does not appear to be germane to the question.

Dr Burnham asked the President to settle the matter since the member from Middlesex East raised objections to the bill and, if the objections were eliminated, the bill would apparently be satisfactory to the members of the Middlesex East Society. It was his idea to have the bill altered by the Committee on State and National Legislation so that it would be satisfactory and the Council could then pass on it.

The Secretary procured the President's permission to speak on the subject under discussion and stated for the information of the Council that the Committee on State and National Legislation could have no part in the alteration of the bill. The bill was prepared by its sponsor, has been entered into the House under its number and has been assigned to a committee for a hearing. The Committee on State and National Legislation of the Massachusetts Medical Society could not obtain the change of a comma, so that any motion which is dependent upon getting a change in the bill is a waste of time.

Dr Burnham withdrew his motion.

Dr Lane, Norfolk, spoke at length recapitulating the objections based upon the amount of the tax pointing out what had happened in the case of other taxes originally enacted for a

specific purpose but subsequently diverted. He stated that he would like to make a motion to the effect that the Massachusetts Medical Society approve of a bill which provides for the appropriation of money for this specific purpose of enforcing the registration law and suggested that all physicians serve as unofficial police officers in their respective districts to discover those who are practicing medicine illegally. He stated, however, that he was not inclined to vote to support the bill as it is now written.

A member from Hampden District expressed his belief that the State should undertake this matter without additional taxation. He stated that the physicians are paying taxes as are other citizens and that in his opinion it was not the size of the tax to which he would object but to the unsound principle of what amounts to a class tax.

President Mongan recalled the Council to the consideration of the question, namely, Is the Council disposed to vote to support House Bill No 35? He then called for a vote and it was quite evident that the motion was lost.

The President asked the Secretary if there were any other communications from the Committee on State and National Legislation. The Secretary stated that the Committee had likewise referred to the Council the question of its attitude toward House Bill 1408 entitled "An Act relative to the Selection of Physicians under the Workmen's Compensation Law." The hearing on this bill was set for February 6 before the Committee on Labor and Industries. The bill was read. The Secretary pointed out that this bill was presented on petition of Representative McDonough who in turn was acting for a member of the Norfolk District Medical Society. This physician was under the impression that, when he submitted his material to Representative McDonough, he was embodying the principle of the New York law which has recently been passed. This law was designed to close certain loopholes that existed in that state. In its present form, however, the bill simply calls for the publication by the Department of Labor and Industries of a list of physicians in each plant that employs labor and provides that this list shall be prepared by the Department and shall include all registered physicians within the several districts who make application to the Department for enrollment.

The President pointed out that this is another bill introduced by one of our members and that this member asks us to support it. It has not been thoroughly studied by the Committee.

Dr Landesman, Norfolk, stated that he felt that it was an excellent bill and that the Society should go on record as favoring it. A Councilor stated that the present law enables any employee to call on any physician whom he may wish and, while he is aware that some of

the insurance organizations in industrial plants tell employees that they have a choice of only one or two physicians the law as it stands permits the employee to be treated by any physician whom he desires to call upon.

The Secretary stated that the bill calls for a subdivision of the State into districts of approximately one hundred thousand population and that if the employed person happens to be in the same district with the physician all well and good, but that in a district such as Metropolitan Boston this is not always the case. A man may live in one district and work in another some distance away. In addition to this, Section 28 says that in the selection of a physician, the employee shall select from the list. He is given no choice. It seemed to the Secretary that this provision is probably unconstitutional because free choice is denied the worker.

The President then called for action on Dr. Landesman's motion which had been seconded. The motion was lost.

Dr. Dutton resumed the physicians present that, since the hearing on House Bill 1404 was set for the next day (February 6) it would be well to convey the general attitude of the Society to the Senators and Representatives.

The President next called for the petitions for restoration to Fellowship and the Secretary reported that Dr. Charles L. Judkins of Lynn had been recommended by Drs. John W. Trask, O. C. Blair and George H. Kirkpatrick. It was voted to restore Dr. Judkins to Fellowship under the conditions laid down in the committee's recommendations. Dr. Sanford M. Liljestrom of Worcester had been considered by a committee consisting of Drs. Ralph W. Ellis, Raymond W. Cutler and John M. Fallon. He was unanimously recommended for restoration under the usual conditions. The Council voted to restore Dr. Liljestrom.

The Secretary reported applications for reinstatement as follows: Dr. John R. Agnew of the Hampden District with suggestion that the committee consist of Drs. W. A. Hare, M. F. Hosmer and E. T. Smith; Dr. George E. Tucker of Salem the investigating committee to consist of Drs. Henry Tolman, Jr., J. Frank Donaldson and D. Scoville Clark; and Dr. R. E. Hubbard formerly of East Northfield and now of Springfield the committee to consist of Drs. John M. Birnie, W. A. R. Chapin and A. G. Rice. The Council voted to approve of the committees suggested in each case.

In the absence of the Chairman of the Committee on Medical Education and Medical Diplomas, the Secretary informed the Council that there was no formal report but that the Chairman, Dr. Fitz, had recommended Dr. Fredrick H. Pratt, Professor of Physiology at Boston University for Honorary Fellowship in the Society. The President stated that according to the rules this name would be referred to the Committee on Membership and Finance.

The President announced that the next item of business would be the election of Delegates and Alternates to the House of Delegates of the American Medical Association for two years beginning June 1, 1936.

Dr. Blaisdell arose to state that he had been informed of the President's intention to make changes in the personnel of the Delegates and among these changes he was considering the elimination of himself. He stated that he could well appreciate the embarrassment under which the President labored in the matter but it would be an irreparable loss to the Society if with his years of knowledge of and participation in the work of the American Medical Association the Society should at this time be deprived of his services. He moved, therefore, to nominate as Delegate to the House of Delegates of the American Medical Association for the term of two years from June 1, 1936, Dr. Charles E. Mongan of Somerville. The nomination was received with applause.

Dr. Tighe seconded the nomination and paid a tribute to the leadership of President Mongan. The President acknowledged the motion and thanked the Fellows for their expression of sentiment. He then proceeded to nominate as his Alternate, Dr. Arthur W. Marsh of Worcester. The other Delegates and Alternates nominated were as follows: Dr. Michael A. Tighe of Lowell, Delegate and Dr. Walter G. Phippen of Salem, Alternate and Dr. Walter A. Lane of Milton, Delegate and Dr. P. P. Henson of Hyannis, Alternate. The Council voted to elect the Delegates and Alternates as nominated.

The President then nominated Dr. A. S. Begg as the Delegate to the Annual Congress on Medical Education and Licensure of the American Medical Association to be held at the Palmer House, Chicago, February 17 and 18, 1936. The Council voted approval.

The President then announced the appointment of Delegates to the Annual Meetings of the five New England State Medical Societies to be held in 1936.

Maine Justus G. Hanson of Northampton.

Hanford Carvell of Gloucester.

New Hampshire E. O. Taber of Lowell.

G. P. Norton of Fitchburg.

Vermont R. J. Carpenter of North Adams.

H. J. Downey of Pittsfield.

Rhode Island E. L. Merritt of Fall River.

Charles Shanku of New Bedford.

Connecticut George L. Schadt of Springfield.

W. F. Lynch of Worcester.

The nominations were approved by the Council.

The President asked the Secretary to read the report of the Joint Committee appointed by the Council of the Massachusetts Medical Society and the Boston Medical Library which was submitted by the Chairman, Dr. Robert B. Greenough. (See Appendix No. 10.) The Council voted to accept the report. The President then decided to refer the report to the

Committee on Medical Education and Medical Diplomas with instructions to report at the next meeting

In the absence of Dr. Roger I. Lee the President called upon the Secretary to present the report of the Committee Appointed to Consider the Type of Person to be Admitted to Fellowship in the Massachusetts Medical Society. The Secretary stated that he had the report which was of a general nature and somewhat extensive and the President ordered that the report be received and published with the Proceedings (See Appendix No. 11.)

The President asked the Secretary to read a communication submitted by Dr. M. Luise Diez, Director of the Division of Child Hygiene, in which a request is made that the Massachusetts Medical Society establish a Section on School Hygiene. The President ruled that this communication should be referred to the Committee on Public Relations with directions to report at the next meeting. His ruling was confirmed by vote.

The Secretary then presented a letter from Dr. Guralnick of East Boston which suggested the possibility of establishing a pension system for physicians. The President referred the matter to the Committee on Public Relations.

Communications received from Dr. W. A. Hutton of Melrose and Dr. Richard Dutton of Wakefield were referred to the Committee on Public Relations.

Dr. Alexander A. Levi, Secretary of the Middlesex South District Medical Society, presented the following communication:

Resolved That the names and addresses of applicants for membership in the Massachusetts Medical Society, together with the names of members of the Society acting as sponsors in such cases requiring this action (in accordance with the By-Laws of the Massachusetts Medical Society Chapter I, Section 1 [and] Chapter V, Section 1 [and] Chapter VII Section 5) and the name and address of the secretary of each district be published in *The New England Journal of Medicine* three weeks prior to each censors meeting.

The necessity for giving publicity to the names of the applicants for membership was stressed by Dr. Levi and substantiated by the President. After some comment as to the time factor in the resolution, it was finally adopted by vote.

The President then announced that Dr. George Blumer of New Haven had been chosen as the Shattuck Lecturer for the next Annual Meeting in Springfield.

The meeting adjourned at 3:35.

ALEXANDER S. BEGG, M.D.,
Secretary

APPENDIX TO THE PROCEEDINGS OF THE COUNCIL

APPENDIX NO. 1

REPORT OF THE COMMITTEE OF ARRANGEMENTS

To the Council of the Massachusetts Medical Society.

Your Committee of Arrangements wishes to report that the plans for the Annual Meeting and Dinner at Springfield on June 8, 9 and 10 are well in hand, and have progressed most favorably. Through the activity of Dr. Stetson and Mr. Robert Boyd, to date forty-four booths have been sold, considerably more than were sold last year at this time.

The local Committee of Arrangements in Springfield, which was appointed by me last fall, has arranged for excellent clinics at the various Springfield hospitals.

The Women's Committee are planning an extensive program of entertainment for the wives and daughters of our members, and a Kicker's golf tournament will be held, which will appeal to all our members who are interested in golf.

Your committee has arranged for all the section meetings to be held in the Springfield Auditorium, together with the Scientific and Commercial Exhibits, which will be of interest to the general practitioner, as well as to the specialists in certain branches of medicine.

After consultation with the President, Dr. Mongan, and the Secretary, Dr. Begg, I called a meeting of the chairmen of all the various sections to discuss the type of papers to be presented in the section meetings, and asked for any suggestions from either the Chairman or Secretary of each section. I have also arranged for the chairman of each section and the officers of the Society, as well as the members of the Committee of Arrangements, to write editorials in their particular fields, for *The New England Journal of Medicine*, so that each individual member of the Society will be informed of what is going to be presented on each day of the meeting.

I have visited practically all of the District Societies with your President, Dr. Mongan, and your Secretary, Dr. Begg, and have been very much impressed by the welcome given your state officers, and with the enthusiasm which has been manifested by District Societies.

We look forward to a most successful meeting in Springfield, and ask for your continued support.

WILLIAM REID MORRISON, M.D., *Chairman*

APPENDIX NO. 2

TREASURER'S REPORT

February 5, 1936

To the President and the Council

The past year, 1935, has been a year of progress in finances, for our Society. There have been, however, a number of difficulties, especially in the reinvestment of available funds. We, in the United States, have experienced unparalleled low money rates, when short term bonds and notes have sold to net a (small) fraction of one per cent, and long, 25 and 30 year, corporation bonds have sold, and are selling, to net less than 3.20 per cent, and savings banks pay only 2½ per cent on deposits. In addition, a number of the bonds, held for years by our Society, with coupons of 5 or 6 per cent, have

been called for payment. These influences have reduced the year's income of the General Fund and the *Building Fund*. The Treasurer hesitates to buy new issues with 3½ per cent coupons and long maturities, at present high yes abnormally high prices when his judgment tells him that, perhaps within a few years the same securities may sell to net 4½ per cent and 5 per cent. Another problem is the serious threat of further inflation in United States currency and credit, by legislation at Washington. Some inflation of credit we already have. Who can tell how much farther we shall go in that direction?

Therefore the investment policy of the Society regarding our funds should be carefully considered, to decide whether the Treasurer shall invest available money in common stocks and equities, to try to take prompt advantage of opportunities as a hedge in case of dangerous inflation or whether the Treasurer should continue to invest, in the hope that wiser and more conservative counsel at Washington, will prevail. The Treasurer has sought advice and suggestion from outside sources from wise bank executives and from men of foresight and long experience. The Society's problem is not too difficult because of the main source of our revenue. In view of the fact, therefore, that our Society receives about 90 per cent of its revenues from annual assessments and only about 9 per cent from interest on securities the Treasurer is of the opinion that our investment policy for the present should continue as in the past, to try to conserve our principal in high grade bonds. He hopes moreover that this policy will meet your approval, and also in the long run, be wise.

Fortunately our Society has escaped taxation. Correspondence between the United States Department of Internal Revenue at Washington and the Treasurer has established the position that our Society is a nonprofit, mutually benevolent and educational corporation. As such, therefore under the United States laws of 1934 and 1935 our Society is exempt from Federal taxation.

The total revenues received in 1935 from annual assessments of resident Fellows amount to \$44,657 the largest sum ever received by the Society from this source. For this result, District Treasurers are to be congratulated. Additional dues received from non resident Fellows amount to \$1,463 so that total dues received in the year were \$46,125. Other revenues received first from invested funds of \$4,194 secondly from proceeds of sales of \$49.50 a gift of \$10.00 and, finally profit (from securities sold and called for payment) of \$787 together amount to \$5,040. Therefore the total gross revenues of the Society from all the above sources (but not including separate income of Building Fund nor dues for Postgraduate Courses) were \$51,166. This, again is the largest such total ever received in one year by our Society.

From dues for Postgraduate Courses the Treasurer received \$2,914. This sum with a credit remaining from 1934 of \$4,233 and the appropriation by the Council of \$1,000 for 1935 (a total of \$8,196) was more than used in the expenses of the Committee on Postgraduate Instruction, with an over draft from funds of the Society of \$831 a total expenditure by the Committee of over \$9,000.

The "*Building Fund*" continues gradually to increase. Income of \$1,850 for the year was added to principal, and with a profit of \$376 brought the Fund to a total of \$55,997 book value, and \$19,347 market value. The increase in prices of high-grade bonds has brought more closely together the book value and market value of our securities, with the result that market value of the *General Fund* is about 100 per cent of cost.

Expenses, during the past year include a number of unusual items which materially increased the total as follows: additional equipment, and rental of new office for the President and for the Secretary; expense of an attorney to work at the State House with the Committee on State and National Legislation; a dinner to the President and President Elect of the American Medical Association; a special meeting of the Council, with Cotting Inncheon and the overdrawn account of the Committee on Postgraduate Instruction. The Treasurer urges therefore, more careful consideration of our expenses for 1936 in the desire for economy and efficiency and in order that expenses will not outrun our revenues. The expenses of the Society in the past three years have increased \$8,000 a dangerous trend.

The Society ends 1935 with unexpended revenues of \$2,441.42. The total assets of the Society amount to \$186,715.10.

Your Treasurer again thanks the officers of the Society and the officers of the District Societies for their coöperation. The past year has been a very busy year in the office of the Treasurer. He is especially grateful for the helpful and loyal assistance on the part of the staff of *The New England Journal of Medicine* without which he could not have carried on the increased work.

CHARLES S. BUTLER, M.D., Treasurer

APPENDIX NO. 3

TREASURER'S REPORT FOR THE TWELVE MONTHS ENDED DECEMBER 31 1935

Hartshorn and Walter
Certified Public Accountants
50 Congress Street
Boston

February 1 1936

The Auditing Committee Dr Richard M. Smith
and Dr Harry P. Cahill

The Massachusetts Medical Society
Boston Massachusetts
Gentlemen

At the request of your Treasurer Dr Charles S. Butler we have audited the books and accounts of The Massachusetts Medical Society for the twelve months ended December 31 1935 and submit herewith

Schedule A Statement showing the Assets and Liabilities of The Massachusetts Medical Society December 31 1935

Schedule B Statement showing the Revenue and Expenses of The Massachusetts Medical Society for the twelve months ended December 31 1935

The cash on deposit in the banks has been reconciled with the bank statements and found correct.

All known cash receipts have been properly accounted for and disbursements are supported by vouchers or canceled checks.

We have made no examination of the securities but are informed by Dr Butler that you have personally examined these securities, also the savings bank books and found them correct.

The attached statements showing the financial condition of the Society on December 31 1935 and the current account for the twelve months ended December 31 1935 are true to the best of our knowledge and belief.

Respectfully submitted
HARTSHORN & WALTER.

APPENDIX NO 4

AUDITING COMMITTEE'S REPORT

To the Council of the Massachusetts Medical Society

The Auditor's Committee has received from Hartshorn and Walter the audit of the books of the Treasurer herewith submitted. It has examined the securities in the hands of the Treasurer as of January 11, 1936 and found all to be present as shown in this account

RICHARD M SMITH,
HARRY P CAHILL

APPENDIX NO 5

REPORT OF THE COMMITTEE ON MEMBERSHIP AND FINANCE ON MEMBERSHIP

At the October 1935 meeting of the Council Rev Francis James Dore, S J, Professor of Biology at Boston College, was nominated for Honorary Fellowship in the Massachusetts Medical Society. Father Dore received the degree of A B from Boston College in 1898, of M D from Harvard Medical School in 1902 and of Ph D from Fordham University in 1918. After graduating from Harvard, he was engaged in the practice of medicine until 1907. He was a Fellow of this Society from 1905 until he resigned in 1907. In the latter year he went to Europe and entered the Society of Jesus at London.

Your Committee heartily endorses this nomination and recommends that Father Dore be elected to Honorary Fellowship.

DAVID N BLAKELY, *Chairman*

February 5, 1936

REPORT OF THE COMMITTEE ON MEMBERSHIP AND FINANCE ON MEMBERSHIP

This Committee recommends

1 That the following named fifteen Fellows be allowed to retire as of December 31, 1935, under the provisions of Chapter I, Section 5, of the By-Laws

- 1 Ayei, Silas Hibbard, Boston

APPENDIX NO 7

REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

The Committee on Postgraduate Instruction wish es to report that the extension courses for 1935-'36 are in progress. The districts have been divided into two divisions, one half had their courses during the autumn, and the other half will have their sessions next spring.

At the present time the Committee is considering the plans for the future of this work and will make the final report at the Annual Meeting in June.

FRANK R OBER, *Chairman*,
LEROY E PARKINS, *Secretary*

APPENDIX NO 8

IMMUNIZATION AGAINST DIPHTHERIA

It is recommended that every child be immunized during the second half of the first year of life with an appropriate toxoid preparation which is injected under the skin and is entirely harmless. This toxoid preparation should be used on any child under twelve years of age.

In children of twelve years or over immunization should be done with the toxin-antitoxin mixture which is also injected under the skin and is also entirely harmless.

SCHICK TEST

A simple skin test called the Schick Test will demonstrate whether an individual has a natural or an acquired protection against diphtheria. If protection exists, immunizing injections are not necessary.

IMMUNIZATION AGAINST SMALLPOX

It is recommended that every child be vaccinated against smallpox during the second half of the first year of life.

It is recommended that this work be done by your family physician.

Family physicians throughout the Commonwealth are organizing to do this and other work in preventive medicine at a price commensurate with the patient's ability to pay.

MASSACHUSETTS MEDICAL SOCIETY

APPENDIX NO 9

REPORT OF THE COMMITTEE ON STATE AND NATIONAL LEGISLATION

Mr President and Members of the Council

Your Committee on State and National Legislation has held several meetings during the Society's current year. The past two months it has endeavored to make a careful study and evaluation of the current legislative list and classified it into legislation which should be favored and which should be opposed. There is considerable proposed legislation of a "reform" or perfunctory nature, or related to one of our allied causes, which consumes much time in its study but which it is deemed best to classify for "no action." Because of pertinent imperfections and because of the diversity of opinion among the Society's members in the matter of two proposed pieces of legislation the Committee decided to render no decision and refer them to you for consideration and your instructions.

These two Legislative Bills are the following:

- 1 H 1408 an act relative to selection of physicians by employees injured in industrial accidents
- 2 H 35 an act for the annual registration of physicians and the publication of a list of registered physicians

Your Committee has given serious thought to the apparent ineffectiveness in securing aggressive or more appropriately progressive legislation. It has given equally serious thought to the ineffective resistance to retrograde legislation. Our legislative ineffectiveness is a very real problem. Your Committee can present your cause at a hearing before a Legislative Committee but unless this is backed up by the physicians among a legislator's electorate our efforts can very readily be of no avail. The Legislator is the representative of the people of a community (this includes its physicians) and it is sad commentary to hear a legislator say in all earnestness, "Well, my family doctor hasn't said anything to me about this," or "Well, the doctors in my district haven't brought this to my attention." The average legislator as well as the average physician wishes to serve his people. It behooves the rank and file of our members to become "politically minded" and take the time to become acquainted with their legislators and talk their medical problems over from the standpoint of public and professional good. It is quite impossible for your Committee on State and National Legislation to make your cause felt unless we have the individual support of our members.

The Committee records with regret that recently at a hearing on H 34, which measure your Society favored to improve medical standards, one of our members saw fit to oppose you in this point of view and so expressed himself at the hearing.

There are certain obligations the Society owes its members and one of these is to keep them informed.

about legislative matters and also it must supply the mechanism for legislative effectiveness. The policy inaugurated last year to give to every member a list of the legislators in his district will be continued. It is also planned to send out to the district legislative committee a bulletin which carries a brief digest of every bill. The society's stand (Favor or Opposed) the hearing dates before committees, also any pertinent remarks on a particular piece of legislation. We believe this will be of considerable practical help as this information will now be condensed and readily available thus avoiding the handicap of gleaning it here and there in our rather voluminous Journal.

Also the Committee calls to your attention the problem of independent presentation of bills by our members without referring them to your legislative committee or any other committee whom you may create or designate. This has given rise to a number of embarrassing situations. For example Two years ago we had three separate Lien laws proposed, each with obvious defects. Then your Society was requested to support these bills. Also members may propose legislation and if your Committee does not come forward with spontaneous support there is the vicious insinuation that we are not sufficiently interested in "The Welfare of the Doctors." Such independent petitions for legislation do not make for uniformity of opinion or support. If this situation is not abated it may be necessary to petition you for some remedial measure.

In conclusion, your committee is at your service. It is always glad to receive suggestions and its present recommendations are that for the best interests of our Society the two before-mentioned proposed legislative measures be submitted to you for consideration.

Respectfully submitted—

D. L. LITTLEBURY

APPENDIX NO 10

The joint committee appointed by the Council of the Massachusetts Medical Society and the Boston Medical Library has had two meetings, and has the honor to present the following report:

It is the unanimous opinion of the members of the joint committee that a closer affiliation between the Massachusetts Medical Society and the Boston Medical Library would be of mutual advantage. The Boston Medical Library is one of the largest and most important medical libraries in this country and contains material relating to medicine in colonial history which is unique. It contains the original library of the Massachusetts Medical Society serves as a reference library for all of the New England States and is used continuously by students and instructors of the three important medical schools in Boston.

Your committee believes that the services of the Boston Medical Library might be and should be made more readily available to all of the members of the Massachusetts Medical Society. There are various ways in which this can be accomplished. For example in connection with the Postgraduate Courses given in the different districts it is suggested that a system of extension service by the library coordinated with the subject matter of the extension courses in each district could be developed at small expense which would greatly increase the interest and the value of the instruction given.

Another plan is to have the library send out packages of books to the districts of the state making some one man responsible for the care and return

of the books so sent. In this way the Fellows of the Massachusetts Medical Society could have an opportunity to see and examine new books as they came out, or perhaps they would prefer groups of books or reprints dealing with one or another special subject. The scheme has many variations.

Meantime bibliographic service for individuals working on a special topic is an important item which needs and deserves closer attention. The point is that whatever the form of service or services may be the library stands ready to undertake to supply it provided only that the Fellows of the State Society will give the project their encouragement and their support.

The joint committee is confident that the successful development of such a service would greatly increase the number of physicians in the state who would find the library of real value in broadening their professional and cultural activities.

Respectfully submitted

APPENDIX NO 11

REPORT OF THE COMMITTEE TO CONSIDER THE TYPE OF PERSON TO BE ADMITTED TO FELLOWSHIP IN THE MASSACHUSETTS MEDICAL SOCIETY

The qualifications for membership in medical societies have been under rather desultory discussion for some years. Apparently there are at present 7014 physicians in Massachusetts according to the thirteenth edition of the A. M. A. Directory. On April 1 1935 there were 4737 members of the Massachusetts Medical Society. Roughly speaking, two-thirds of the physicians of Massachusetts belong to the Massachusetts Medical Society. There are of course three possibilities: (1) To allow things to go on as they are, which is more or less drifting. (2) To try to encourage membership so that a larger proportion of the listed physicians would be members of the Massachusetts Medical Society in support of this view it is urged that the Massachusetts Medical Society would be in a stronger position if it were more truly representative of the total number of physicians and secondly although men might be poorly qualified either from their medical training or from their practice nevertheless, by membership in the State Society these individuals might be improved and reformed and thus be made desirable and worthy members. (3) The third possibility is to scrutinize more carefully than has been done in the past the candidates for election to the District Medical Societies. It can be pointed out that once a man is a member of a District Medical Society it is extremely cumbersome as well as difficult to terminate his membership if he objects. It is likely that there are in the Massachusetts Medical Society and every other state medical society a small proportion of undesirable members who probably do harm to the profession and to the society.

The Committee on Medical Education and Medical Diplomas has been much concerned in regard to its relationship to this problem. This Committee passes on the educational qualifications in general

avoidance, always, of any unnecessary instrumentation

Oral medication

There is little agreement over the value of any particular oral medication. Sandalwood oil in 5 to 10 minim doses, three times a day, after meals, is the most widely used. It is said to relieve urgency and reduce discomfort when, in the early stages of a posterior urethritis or an acute prostatitis, those are annoying symptoms. Whether the fluid intake must be reduced to provide for effective concentration of the oil in the urine, and whether such reduction in fluid intake is in itself a serious disadvantage, is a much debated subject.

Alkalies, balsams, bromides, hyoseyamus and various other drugs also find some use as urinary sedatives. Perhaps the best that can be said of oral medication is that if one of the urinary sedatives relieves the patient's discomfort, its administration may be worth while.

As a rule, unless there are special contraindications, it is considered advisable to increase, considerably, the patient's daily intake of water. Any contraindications must be learned by experience as they vary from patient to patient.

Urethral medication

The objects of urethral medication are to remove the accumulation of pus in which the membranes are bathed, to provide free drainage, to improve local circulation, to stimulate, mildly, the membranes, and least of all to kill the gonococcus (except those on the surface) by any direct antiseptic action. Any drug powerful enough to kill the gonococcus in the depths of the mucosa will add to the damage already being done to the membranes by the infection.

Nonirritating, nonstinging drugs, in dilute solution, at a temperature comfortably warm, injected without force, through suitable syringes or irrigators, give good results. Irritating drugs, astringents, strong solutions, high pressure injections, too much heat or too little, and improper instruments only add to the patient's discomfort, delay cure and cause complications.

For best results, no patient should be permitted to inject medication into his own urethra. Patients may inject too much, thus overdiluting and traumatizing the urethra and often forcing pus into the posterior urethra. Posterior extension, prostatitis and epididymitis may result. Other patients will inject insufficient medication or neglect treatment.

However, many patients cannot afford to pay for or give the time to frequent visits to the doctor's office. Compromise is necessary in these cases, but it must be permitted only in the treatment of the anterior urethra.

A proper syringe preferably a rubber bulb, one-diam, glass syringe of the "Asepto" type,

should be prescribed (or better, dispensed) and insisted upon. The patient should be taught, by actual demonstration in the doctor's office, how to inject and hold the medication. The amount which can be injected safely into a given patient's urethra (they all vary in size) must be determined accurately. Some simple method must be devised by which the patient may always measure the same amount. He should be taught to cleanse and boil the syringe after each use. It may be advisable to give some patients written instructions for the entire procedure.

If the patient is allowed to treat his own urethra, he must be warned to stop all treatment at once and report to the physician if there is any exacerbation of discomfort or discharge or any evidence of extension or complication.

Among the drugs which the patient may use, the organic silver salts (argyrol, silver nucleinate, protargol and neosilvol) enjoy the widest use. Which of these is to be prescribed depends largely upon what the patient can afford, and how important it is to avoid staining of the clothing. Argyrol and silver nucleinate will stain fabrics. Silver nucleinate is the less expensive. Protargol and neosilvol are cleaner. The latter is the more expensive. Argyrol, silver nucleinate and neosilvol may be used in strengths up to 10 per cent although the weaker (5 per cent) solutions are safer for routine use. Protargol may be used in strengths of one fourth per cent to one half per cent.

Urethral irrigation should be done only by the physician. An irrigating tank is safer than a syringe as it cannot deliver the irrigant at a pressure greater than the weight of the column of fluid. The fluid column should never be higher than two, or at the very most, three feet above the level of the urethra.

Irrigation of the anterior urethra is given through a tip which fits into the meatus. Anterior-posterior irrigations are best given through the same type of tip. The patient can be taught, in most cases, to relax the cut off muscle for posterior irrigations. Except in the hands of a highly qualified expert, a catheter should never be passed into the urethra until the urethral infection has subsided and it is necessary to fill the bladder preliminary to prostatic massage. Any instrument passed into an inflamed urethra is certain to cause damage. More strictures have been caused by injudicious instrumentation than by the disease itself. As the treatment of gonorrhea becomes more gentle, strictures become progressively fewer in number.

Potassium permanganate in strengths of from 1:10,000 to 1:8000 is by far the most satisfactory irrigant in use and has stood the test of time. Silver nitrate, 1:10,000 is also useful. A variety of other drugs have enjoyed sporadic popularity, but possess no advantages and some

disadvantages over potassium permanganate. The temperature of the irrigant should be as high as the patient can stand with complete comfort—usually not higher than 110 degrees F (in the reservoir).

If the infection is active in the posterior urethra when the patient is first seen or it extends into the posterior urethra later, all direct treatment of the urethra must be omitted until the activity has subsided. Thereafter the patient may continue to treat his anterior urethra if necessary, but the physician must give the anterior posterior irrigations.

Dressings

The patient who has a urethral discharge is disturbed over the soiling of his clothes. The physician should appreciate this and provide for it in order that objectionable dressings will not be used.

The dressing has only esthetic value and it must not be allowed to interfere with drainage or treatment. A sanitary bag (gonorrhea bag) may be prescribed, into the bottom of which gauze (not cotton) may be placed. The gauze should be replaced by a fresh supply after each urination. A butterfly dressing will collect urethral discharge, but will not protect the clothing against the stains of colored medications. A hole is cut in the center of a strip of gauze, the glands slipped through the hole and the foreskin pulled down to hold the dressing in place. The gauze should project from the penis in sufficient quantity to collect the pus which accumulates between at least frequent urinations.

Prostatic massage

When the urethral infection has subsided and is under control or it is obvious that there is no further progress toward cure the prostate is examined and if it has been infected it is treated by massage. The prostate is always infected if the infection extends into the posterior urethra.

The object of prostatic massage is to free the prostate of infection. This is accomplished partly by the gentle evacuation of its contents (thus improving drainage) and gentle stimulation of circulation to relieve congestion.

Here, as in any stage of the management of gonorrhea, gentleness is essential. Massage should never be so strong as to cause pain. It should never be vigorous. It should be begun lightly and limited at first to a very few strokes. The pressure may be increased and the massage more thorough with time and ability of the patient to stand it with comfort.

Proper massage may or may not produce a visible discharge of fluid at the urethral meatus. Examination of the urine or irrigant voided after the massage will give ample evidence of the evacuation. If the patient has had treatment elsewhere, it may be well to explain this

point as some patients have been allowed to believe that a massage which does not produce a visible evacuation is not adequate.

Proper prostatic massage is an art. It can be learned only by patience and experience.

Careful study of many cases has disclosed that the vesicles are more often involved following a posterior urethritis, than it has been generally supposed. It seems improbable that they could escape at least some degree of infection in view of their relation, like that of the prostate, to the posterior urethra.

Seriously involved vesicles may be palpated rectally, above the upper border of the prostate. If they can be palpated, great care should be taken to leave them alone so long as there is any evidence of activity, for epididymitis may follow injudicious meddling. If they cannot be palpated, their involvement may be indicated by the amount and nature of the detritus in the urine voided after massage. Poorly draining vesicles may cause backache or referred pains which sometimes lead to mistakes in diagnosis.

When it is safe to treat the vesicles they can be stripped during prostatic massage by carrying the massaging finger as far above the upper border of the prostate as possible.

There should be some fluid in the bladder when the prostate is massaged as the urethra should be cleansed by emptying the bladder through it after massage. Urine is the best irrigant at this time. The unnecessary filling of the bladder with an irrigant adds only to the dangers of unnecessary trauma.

If the patient has emptied his bladder or if the physician must examine the urine prior to massage (two-glass test) the bladder should be partly filled before massage. The routinely used irrigant may be used for this purpose. If the patient and the physician have learned to fill the bladder through a meatal tip so much the better. Otherwise a small sterile, soft rubber catheter, well lubricated may be passed into the urethra beyond the cut-off muscle (without using force) and the bladder partly filled through it. Instrumentation, or the passage of a catheter is usually contraindicated if the urethral infection is still active.

MISCELLANEOUS TREATMENT

Sitz baths are excellent for the relief of an acute posterior urethritis or prostatitis. They add to the comfort of the patient and improve the circulation of the affected parts.

Sounds have no place in the treatment of an active urethral or prostatic infection. Their use should be limited entirely to

- 1 Therapeutic test for cure after all signs and symptoms of infection have disappeared.
- 2 For the treatment of stricture after any active infection has subsided.

- 3 In the hands of the expert, the urethra may be massaged gently over a sound, if, in a long-standing, persistent, low-grade infection, it appears that submucous infiltration is the cause of failure to improve. Other causes of persistent infections must be ruled out first, such as, a prostatitis, misconduct on the part of the patient, overtreatment and too vigorous treatment. The urethral infection must first have received adequate routine treatment until it is evident that no further improvement is to be expected.

Vaccines, foreign proteins, filtrates, diathermy and other special or widely promoted drugs or methods have no place in the routine treatment of gonorrhea. Vaccines, foreign proteins and filtrates may be of use in the treatment of certain complications, such as arthritis or epididymitis. Diathermy may be useful in epididymitis. Dilators had better be discarded as obsolete and dangerous except as surgical instruments in the hands of trained urologists.

Meatotomy

Rarely, even in a large practice, may it be necessary to enlarge the urethral meatus (meatotomy) in order to promote drainage.

RECORDS

It is impossible to judge of results by impression alone. That physician will best adjust his methods to eventual success who keeps careful records and who studies them for results.

The minimum record should consist of at least the following:

- 1 History of the infection
- 2 Examination of the patient with particular emphasis upon the genito-urinary system
- 3 Laboratory findings
- 4 Diagnosis
- 5 Treatment, by date and treatment used
- 6 Conduct of the patient
- 7 End-results, with a summary of the progress of the case

These records should be studied from time to time with the following questions in mind:

- 1 Proportion of patients neglecting treatment?
- 2 Proportion of patients cured?
- 3 Stage of infection when first seen?
- 4 Proportion of patients having had previous treatment and with what results?
- 5 The time required for cure? Relation of the patient's conduct to the time required for cure?
- 6 Tests which most satisfactorily indicate cure?

- 7 Relation of good results to the kind of treatment?
- 8 Relation of poor results to the kind of treatment?

SUMMARY

On the whole, the fundamental principles of the successful management of gonorrhea in the male are the following:

- 1 Good conduct on the part of the patient with especial emphasis upon abstinence from any form of sexual excitement and alcohol
- 2 Proper evaluation of any previous treatment
- 3 Regularity and continuity of treatment
- 4 Careful instruction of the patient concerning any treatment which is to be self-administered
- 5 Gentleness
 - (a) Mild solutions, nonirritating and nonastringent
 - (b) Suitable syringes and irrigators which avoid traumatization of the inflamed membranes
 - (c) Avoidance of force in giving injections and irrigations
 - (d) An irreducible minimum of urethral instrumentation
 - (e) Gentle prostatic massage

SHORT CUTS

In addition to the above, it is urgently recommended that the physician familiarize himself with a simple plan of routine treatment in the giving of which he may become proficient. It is further suggested that he turn a deaf ear to the high pressure salesman who appears every month or so with a new "cure-all" or a new addition to the therapeutic armamentarium. The innumerable offerings of the past have passed quietly into oblivion after enjoying a brief hour upon the stage, leaving behind them distrust, disappointment and uncured patients. If the future produces anything sufficiently sound to deserve a permanent place in the management of gonorrhea, its announcement will come from those of the medical profession who are qualified to judge, after adequate experience, of its value. The pronouncements of non-medical, clinically ignorant manufacturers of drugs, backed by the alleged testimonials of physicians who are in no sense qualified by experience to testify, should be given the little consideration which they are worth. Many of the high-pressured concoctions of the past and present have enjoyed large sales. They may have enriched their producers, but they have not contributed to the more successful management of a disease which has too long been the football of the quack and the drug-house. It is time that the management of gon-

orrhea became a medical problem. It is time that the medical profession began thinking a straight way through the maze of colored solutions, pills, and tradition instead of darting to the right or to the left at the appearance of every dazzling therapeutic signpost which shrieks hysterically "this is the way." The only way to the successful management of gonorrhea known today has been outlined in prin-

ciple, here. There are no short cuts. Those byroads which appear to be short cuts lead only to dead-ends or to the ravine called "complication."

The next paper by The Neisserian Medical Society will consider the treatment of gonorrhea in the male step by step, in detail, for the various stages of the infection.

A REVIEW OF THE CARDIAC DEATHS IN 1,245 MEDICAL EXAMINERS' CASES THAT HAVE COME TO AUTOPSY IN THE MASSACHUSETTS STATE HOSPITALS FOR MENTAL DISEASES*

BY ANNA M. ALLEN, M.D.†

WITHIN the last twenty-one years out of 1,245 Medical Examiners' cases which have come to autopsy in the State Mental Hospitals of Massachusetts, 154 or approximately 12.4 per cent have shown cardiac lesions, single or combined in the main causes of death. These were classified from the cause of death on the certificate under headings indicating the structures involved. (See Table 1.)

TABLE 1

Pericardial deaths	8	{ Acute	7
		{ Chronic	1
Mycocardial deaths	71	{ Chronic myocarditis	40
		{ Acute dilatation of the heart	14
		{ Fatty degeneration	8
		{ Cardiac rupture	7
		{ Acute myocarditis	2
Endocardial deaths	38	{ Acute vegetative endocarditis	7
		{ Chronic	31
Coronary disease	57	{ Sclerosis	33
		{ Occlusion	24

In viewing this table please note that in many cases two cardiac conditions were given in the cause of death as for instance—coronary sclerosis and chronic myocarditis, and that these are here listed separately.

Pericardial deaths are listed eight times, all except one of these being acute and with effusion. The pericardial condition was unsuspected in life and would have been undiscovered without autopsy illustrating as Osler says:

There is probably no serious disease so frequently overlooked as pericarditis with effusion.

Mycocardial deaths totaled seventy one. Under this heading there are forty instances of chronic myocarditis. In the majority of these chronic cases fibrous replacement had presumably occurred secondary to coronary sclerosis.

Presented at the meeting of the Massachusetts Medical-Legal Society, October, 1925.

*Allen, Anna M.—Formerly Pathologist, D. V. State Hospital and Massachusetts Department of Mental Diseases. For record and address of author see "This Week's Issue," page 531.

In two syphilis was present. *Acute cardiac dilatation* was given as the cause of death in four teen instances. In some this had occurred following convulsive seizures; in other cases it occurred in association with endocarditis, influenza, heat prostration, postencephalitis, etc. *Fatty degeneration* was listed in the causes of death eight times. Death occurred quite suddenly, and at autopsy the heart muscle is described as being very soft. It is possible that in many of these the softening of the muscle was due to postmortem change as most of the autopsies were performed more than eight hours after death and microscopic examination was not made to confirm the diagnosis. Chronic endocarditis and coronary sclerosis were also present as associated pathology in some of these cases. *Cardiac rupture* occurred seven times. The left ventricular wall had broken through in all of these and in each case coronary sclerosis was present. Associated trauma may have been a factor in one case in which two ribs were broken on the right side and a laceration of the liver was found but here also the left ventricular wall was fibrous and thinned out in the region of the tear. The rupture frequently occurred at the edge of an aneurysmal dilatation in the ventricular wall the aneurysm being situated over an area in which fibrous replacement had occurred as the result of coronary artery occlusion. *Acute myocarditis* mentioned twice might perhaps be listed as suppurative myocarditis. In both there was abscess formation in the wall of the left ventricle, one which occurred secondary to a purulent pericarditis and the other in association with a vegetative endocarditis.

Endocardial deaths totaled thirty eight. Acute vegetative endocarditis was given as the cause of death seven times. Chronic endocarditis was present in thirty one. The mitral valve alone was affected in fifteen cases, aortic valve alone four times and both valves together were diseased in eleven cases. One case of congenital valvular disease, aortic, died suddenly.

Coronary disease was held responsible for fifty-seven deaths, of which twenty-four were found to have a definite occlusion in the major branches. The occluding agent was usually a thrombus, but occasionally a softened atheromatous plaque was described as obliterating the lumen. The left coronary artery was occluded in eighteen cases, and the right coronary artery in the remaining six.

A brief analysis of the age at death in this group shows that only eight or less than 5 per cent were under forty years of age. The average age for the total group was 62.6 years. The youngest was twenty years of age and the oldest eighty-eight years. For the group with coronary thrombosis the average age when death occurred was 65.3 years. The youngest death from coronary occlusion was forty-nine years and the oldest seventy-six years. With regard to sex, ninety-five males and fifty-nine females died suddenly from cardiac lesions.

The most striking fact that comes to light in this review is the comparative infrequency of sudden death from acute coronary occlusion in mental patients. No explanation of this is vouchsafed though reference may be made to the paper by Donald Gregg, "The Lethal Power of the Emotions,"* presented before the American Psychiatric Association, Washington, D. C., June 1935. He gives the incidence of coronary sclerosis and angina pectoris in the general population as 13.8 times greater than that of the State Hospital population. He also points out the predominance of endocarditis, myocarditis and general arteriosclerosis in mental patients and suggests that this may be due to the age factor and to the fact that cerebral arteriosclerosis brings many cases to the hospitals.

In those cases dying suddenly with coronary occlusion the lumen of the artery was occluded within a few centimeters of its origin from the aorta. Coronary sclerosis without occlusion, while frequently listed as an incidental finding at autopsy, was given as a cause of death in only thirty-three cases.

It appears impossible to make a valid correlation of the psychosis and the cardiac death, but regardless of this a table is presented giving the number of sudden cardiac deaths for

*Mental Hygiene 20: 30 (Jan.) 1926

each psychosis. The average age at death is given also, but where the number of cases drops below fifteen the average is likely to be affected by the small number of cases. It

PSYCHOSES IN 154 CARDIAC DEATHS

Psychosis	Number	Average Age at Death
Dementia Praecox	48	60.5 years
With Cerebral Arteriosclerosis	20	66.6 "
Senile Dementia	16	74.2 "
Manic Depressive	15	59.2 "
Alcoholic	15	63.2 "
Mental Deficiency	9	50.0 " *
With Other Brain and Nervous Disease	7	50.4 " *
With Somatic Disease	5	66.0 " *
Undiagnosed	5	64.9 " *
Epilepsy	4	53.5 " *
Involution Melancholia	4	64.5 " *
General Paralysis of the Insane	3	49.6 " *
With Psychopathic Personality	2	47.0 " *
With Brain Tumor	1	67.0 " *

154

*May be inaccurate because of the small number of cases used in making the average.

might be mentioned in passing that seven cases out of forty-eight of dementia praecox died of coronary occlusion and that three cases out of four of involution melancholia died with the same condition.

SUMMARY

1. Within twenty-one years 1,245 Medical Examiners' cases have come to autopsy within the Massachusetts State Hospitals for Mental Diseases.
2. Cardiac lesions caused death in 154 or 12.4 per cent of these.
3. Coronary occlusion was a cause of death in only twenty-four cases.
4. (a) The average age at death for the total group of cardiac deaths was 62.6 years.
(b) The average age at death for those with coronary occlusion was 65.3 years.
5. There were ninety-five males and fifty-nine females in this series.
6. As for type of psychosis, dementia praecox headed the list, forty-eight in number.

REPORT OF A PERFORATION OF THE UTERUS WITH PROTRUSION OF THE APPENDIX THROUGH THE HIATUS

BY FREDERICK DJERF, M.D.*

THIS is a résumé of a case of perforation of the uterus with the vermiform appendix protruding through the hiatus. Examination of the literature discloses many cases of perfora-

*Djerf, Frederick—Junior Visiting Surgeon, Burbank Hospital, Fitchburg. For record and address of author see This Week's Issue, page 544.

tion of uterus, but none of this nature, so far as the writer has found.

CASE No. 67855. Burbank Hospital, Fitchburg. A para-4 twenty-eight year old woman entered my office in mid June, 1935, with a history of amenorrhea of six weeks' duration. Examination revealed

enlargement of the uterus Hegar's and Chadwick's signs plus a long partially prolapsed cervix. This woman had been delivered normally in April 1934 of an eight pound six ounce boy. Her physician had informed her that all signs indicated a pregnancy.

On September 8 1935 while I was not on duty she was admitted to the Burbank Hospital because of vaginal bleeding of two weeks' duration. She admitted that some mechanical manipulation had been performed on her and that she had passed placental tissue and a fetus. She had had frequent chills and sweating spells for the past two days.

On entrance, examination revealed a fairly well developed and well-nourished young woman lying propped up in bed complaining of generalized weakness and cramps in the lower abdomen.

Her face was drawn anxious and ashen. The mucous membranes of lips and conjunctivae indicated marked anemia. The skin was hot and moist, the tongue dry and coated and the throat normal. Visible pulsations were apparent on the right side of the neck. The lungs were clear and resonant with no rales, the heart of normal size without adventitious sounds and of good quality with a rate of 134.

The abdomen was level with tenderness over the entire lower part, and markedly tender above the symphysis but not rigid or spastic. There was a moderate serosanguineous vaginal discharge of a sweetish odor. No vaginal examination was performed. The temperature was 104 respirations 24. Urine clear pale yellow 1002, no albumin, no sugar. Microscopic examination of sediment negative.

Blood Hgb 80 Tallqvist, white blood count 16750 and red blood cells 1930 000.

The patient was given shock treatment and by the twenty-sixth of September had improved with temperature normal for five days, pulse 80 to 90 with the blood picture much better. There persisted however an increasing flow of blood from the vagina so that an examination under ether was indicated in order to determine the advisability of a dilatation and curettage.

Under gas-oxygen anesthesia, the patient was placed in lithotomy position and prepared locally for examination. Digitally the cervix was found about one inch within the vaginal canal. The uterus was enlarged to that of a two months pregnancy soft and boggy. After insertion of a weighted speculum and, grasping the anterior lip of the cervix with volsellum forceps an elongated rounded piece of tissue not unlike a cord, protruded through the os. This was gently drawn down and found to consist of the appendix and meso-appendix.

The patient was hastily placed in Trendelenburg position and consultation arranged with Dr. A. P. Lowell of Kitchburg. On opening the abdominal cavity he found old clots of blood in the pelvis with the caecum resting on the surface of the uterus between cornua. On gentle retraction the appendix was withdrawn from the uterine cavity showing a perforation of the uterine body with ragged edges and one half inch in diameter. Free bleeding from the edges of the wound was in progress. Due to the condition of the patient, hysterectomy was deemed unwise. The perforation was closed with purse-string and through and through chromic No. 2 sutures. The appendix was removed in routine fashion and two drains inserted into the pelvis. The abdominal wall was closed in layer sutures about a drain.

After a stormy convalescence the patient was discharged and one month after the operation was in good condition.

Grossly the appendix measured 10.5 by 17 cm. The serosa was covered with a thin layer of fibrin. The tip was somewhat darkened the lumen patent throughout, containing soft fecal material. The mucous membrane was intact. The condition of the appendix indicated recovery from a former appendicitis with acute peripendicitis.

Reconstruction of the situation led us to believe that some instrument had perforated the uterus when an abortion was performed and the appendix had slipped through the opening and sufficiently plugged the orifice to prevent bleeding. This undoubtedly saved the patient's life.

MOTHER'S DAY (Continued from page 526)

- 5 Examination of the mother at six weeks three months six months and one year after the baby is born.
- 6 Arrangements for continuous medical supervision of the baby.

UPON WHOM DOES RESPONSIBILITY REST?

First, upon the prospective parents themselves. One of the purposes of this special Mother's Day effort is to tell expectant mothers what care they should have. The late Dr. Whitridge Williams of Johns Hopkins University said: "When the women of America realize the value and need for maternity care they will demand it. Then and only then will they get it."

Secondly upon the medical profession generally and each member of that profession who cares for pregnant mothers. This group as a whole is struggling virtually unaided in many communities.

Thirdly the social and health agencies public and private. The duty of this group is to find mothers in early pregnancy and to direct them to places where adequate care is given.

Do not let another Mother's Day pass without taking the first step in your community toward making maternity safe.

The Maternity Center Association 1 East 57th Street, New York City upon request will gladly supply suggestions for the conduct of special Mother's Day educational efforts in local communities.

REST FOR THE TUBERCULOUS LUNG

Rest for the diseased areas of the lung—which means complete rest for the individual—is the basis of the modern cure for tuberculosis. The reason the fight against this disease has been such a long and hard one is not that science is without enough knowledge but it is difficult for people to be persuaded to accept this knowledge. The disease is not a dramatic one. Quick saving of lives by an emergency operation or the injection of a single dose of nutritive, appeals to the public more than the slow patient battle against tuberculosis. Silence as a human quality does not make a big hit at the movies.—*Bulletin N Y State Medical Society*

CASE 22111

PRESENTATION OF CASE

A sixty year old white Canadian janitor entered complaining of abdominal pain.

He had been perfectly well until six weeks prior to entry. At that time he began to lose his appetite and, three weeks later, he noted a dull aching intermittent epigastric pain which seemed worse in the late afternoon and had no relation to meals. It spread to the right upper abdomen and flank, and gradually lessened in intensity. Four weeks after the onset he vomited some greenish material. Emesis occurred three or four times thereafter. During the week preceding admission he was nauseated continually and became progressively weaker. For an indefinite period his bowel movements, which had previously been quite regular, became costive. The stools were normal in appearance. He believed that he had lost considerable weight since the onset of his illness. No other symptoms were elicited.

He had been in the hospital two and a half years before this present admission because of cellulitis and gangrene of the penis following sexual exposure. Incision and drainage and finally amputation of the glans were done. Hinton and Wassermann tests were negative.

Physical examination showed a drowsy, moderately jaundiced man in no acute distress. (The patient had not known that he was jaundiced.) His lips were bluish in color and cracked. His pupils were slightly irregular but reacted promptly to light. Examination of the fundi exhibited narrowing of the arterioles with nicking of the veins. The lungs were negative except for some dullness at the right base posteriorly. The heart was enlarged to the left but was otherwise negative. The blood pressure was 125/85. The liver edge extended three fingerbreadths beneath the costal margin and was stony hard in consistency. One examiner noted questionable palpation of the gallbladder. The prostate was said to be small and nodular.

The temperature was 99.5°, the pulse 90. The respirations were 20.

Examination of the urine showed a specific gravity of 1.030 and was otherwise negative. Later specimens showed increasing amounts of

bile. The blood showed a red cell count of 5,800,000, with a hemoglobin of 90 per cent. The white cell count was 18,000, 82 per cent polymorphonuclears. The stools were watery, light brown in color, but were otherwise negative. There were negative reactions to guaiac tests upon several specimens. The serum protein was 5.2 grams per cent. A van den Bergh showed 9.37 milligrams per cent of bilirubin, direct reaction. The blood cholesterol was 312 milligrams per cent. The sedimentation rate was 1.04 millimeters per minute.

A barium enema was negative. A gastrointestinal series showed no evidence of organic disease. Films of the vertebrae showed marked hypertrophic changes of the lower dorsal spine but no evidence of metastatic malignancy.

The patient became progressively weaker and the van den Bergh rose to 16.5 milligrams per cent. Thereafter the patient continued to go downhill and died on the eleventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR. CHESTER M. JONES: The very shortness of the story is quite important; it seems to me

A person who comes in with upper abdominal pain of six weeks' duration at the age of sixty immediately makes one think of malignancy, and very frequently malignancy of the stomach, but it is quite unusual not to have some relation between the intake of food and occurrence of pain. If this patient has disease in the stomach I shall be surprised because of that one fact. I have no idea why the pain became less severe. One certainly has to include in the differential diagnosis disease of the organs in the right upper quadrant.

Things are happening rather rapidly here and it would seem to me that the vomiting, particularly of green material, must indicate that the bile passage was open or nearly open, and in the second place, if the vomiting is on an obstructive basis, the obstruction must be below the common bile duct. It does not sound like the vomiting of cancer of the stomach. I would rather think of some disturbance around the duodenum causing right upper abdominal pain and also enough irritation to cause vomiting.

"For an indefinite period his bowel movements, which had previously been quite regular, became costive." If that indefinite period means months, it is of some importance because it means there was trouble in the gastrointestinal tract for a long time. Change in bowel habits very frequently is the first symptom in cancer of the gastrointestinal tract and may precede any other symptoms by months.

From the story alone I think the important points to summarize are the following: that the history is short in duration, that it is associated with discomfort and dull pain rather than sharp colicky pain, that the pain apparently has no relation to meals and shifts to the right side, and

that there is a story of vomiting the vomitus containing bile but no blood. That certainly would make me feel that there is something wrong in the region of the duodenum. It may be the pancreas. It may be the duodenum itself. It may be the gallbladder. It may be the liver. If there is disease of the pancreas it is rather curious that that pain was not in the back rather than the front. It seems to me that most patients with pancreatic cancer if they have pain at all tend to have it in the back. The rapidity with which it has progressed in this case is still in favor of malignancy.

It seems that the past history has no relation at all to the present admission. It probably represents infection of the penis and one not specific in nature.

Jaundice was so slight that the patient did not notice it. The fact that he was drowsy might, however, indicate that he was cholemic whatever that means. It may mean only that he was dehydrated and pretty sick. The lips were cracked either from fever or dehydration. He has reason for dehydration with a certain amount of vomiting and lack of food intake.

"The lungs were negative except for some dullness at the right base posteriorly." That may mean one of three things: fluid in the pleural cavity due to something underneath it; it may mean a large liver raising the diaphragm and causing fluid at the base, or it may mean subdiaphragmatic abscess of some sort.

The enlargement of the heart is not surprising in view of the fact that he is sixty. He has a certain amount of arteriosclerotic heart disease, but it probably does not enter the picture as a cause of symptoms at all.

There is no mention of the upper border of the liver and I think that is something we almost always forget to put into our records but I am assuming, because of signs in the back, that it was up, and that there was enlargement of the liver to explain the dullness at the right base. The fact that it was stony hard is extremely important. It is hard to palpate a liver and describe it with any real degree of accuracy. The liver edge is not described as soft and I think that is of very real importance. No nodules are described and I think the examiner left them out purposely. It is a very difficult thing to be sure of nodules and the examiner is usually wrong when he says they exist. They are occasionally felt and described but usually are subcutaneous rather than hepatic nodules.

If the gallbladder was felt that is an important physical fact. It is difficult particularly for the average man on the medical ward to be sure he is feeling the gallbladder. We are not accustomed as the surgeons are to feeling the gallbladder but if it were gallbladder it brings out the question of what is causing such

an enlargement. It can be enlarged very rarely from association with gallstones but that is very unusual and it usually is taken to mean and quite correctly, that there is a blocking of the flow of bile and that the gallbladder is fairly normal, the blockage is usually due to cancer of the head of the pancreas. I was interested in looking up Courvoisier's law to learn that Cecil does not include it at all in his index. Osler does and it is worded in various ways elsewhere. Probably it should be stated that in the absence of pain and in the presence of jaundice and a palpable gallbladder the cause is probably malignancy.

If the prostate was nodular it seems to me that is an important point although I am not sure it explains the rest of the picture. A nodular prostate should raise the question of cancer. There is no mention as to whether it was hard, but usually a nodular prostate is hard.

DR. BENJAMIN CASTLEMAN: A urological consultant did not think it was cancer.

DR. JONES: The urine examination fits in with the picture of dehydration perfectly well. It also shows that the jaundice was increased and whatever was the cause of the jaundice it was progressing. The high specific gravity was proof of dehydration.

The fact that the stools were described as brown should be taken as a proof that there was no complete biliary tract obstruction. If that is true it means that the jaundice was an intrahepatic jaundice. One can have a very marked degree of jaundice such as in acute yellow atrophy and still have brown stools, whereas complete obstruction with deep jaundice we associate with clay-colored stools. If the stools were brown it is definitely against jaundice being due to obstruction of the common bile duct and suggests that there is involvement of the liver itself.

The stool examination is of some importance. It seems to me as a negative finding. It does not rule out cancer of the gastrointestinal tract but it is certainly against it. A cancer which has caused enough involvement to make the patient as sick as he is by this time should be ulcerated and should be bleeding if it is primary in the gastrointestinal tract.

I do not think the direct van den Bergh reaction is of any diagnostic significance. The blood cholesterol is high. It can be demonstrated in any degree of liver disturbance but is not diagnostic in itself.

The sedimentation rate is about three times the normal. It is not diagnostic in any sense, coming with infection or with parenchymatous changes in one organ or another. It simply indicates how much cellular disturbance there is. It is important because if surgery is to be considered here is a patient who represents a real risk from spontaneous bleeding.

The story so far is one of involvement of the liver in a patient with a very short story and with jaundice. If the gallbladder is palpable it suggests cancer of the head of the pancreas more than anything else. But if there is cancer of the pancreas it is not causing complete obstruction because the stools have bile in them. Therefore, some of the jaundice must be explained on involvement of the liver itself, and very marked involvement, because metastatic disease in the liver rarely produces evidence of liver disease until it is diffusely spread through the entire organ.

A barium enema was negative and a gastrointestinal series was negative. So far as could be determined there was no evidence of malignant disease in the gastrointestinal tract, one of the commonest sources for metastatic cancer of the liver.

I think the striking feature in this case is the rapidity with which conditions progressed. Here is a story of practically two months in a patient who was up, was perfectly well two months before, and at the end of two months died of a disease which produced jaundice, emaciation, dehydration, and marked involvement of the liver without much pain, I believe he has cancer without much question, and the most important reason for saying so is the shortness of the story and the degree of sickness he presents. The question is where is it primary, and on statistics alone it would seem to me that cancer of the pancreas would be the most logical place to mention as a primary source. On the other hand we would expect, with cancer of the pancreas, jaundice, and a palpable gallbladder, not to find bile in the stools. It is true you may have cancer with jaundice and have a remission so that the jaundice disappears and reappears some weeks or months later but that is unusual. I do not believe he has malignant disease of the gastrointestinal tract with secondary involvement of the liver. It is possibly in the bile ducts or gallbladder with metastases to the liver. My own impression is that almost always if there is cancer of the gallbladder there is apt to be a preceding story of gallstones. This man had no story suggesting gallbladder disease prior to entry to the hospital. I do not know how sound an impression that is to base a diagnosis on but for that reason I am going to say it is more likely to be of the bile ducts than of the gallbladder, and as a possible second bet, cancer of the pancreas. The liver must be very much involved. Of course it is damaged still further by the fact that he is dehydrated, undernourished, the glycogen all gone presumably, but if the jaundice is intrahepatic to a large degree, it seems there must be striking involvement of the liver with fine metastases and that would be very obvious at autopsy. I think he died of liver insufficiency. I was quite interested in looking up one or two cases of so-called

acute yellow atrophy to find one where there had been stone in the common duct with complete obstruction and death from prolonged jaundice with typical histologic findings of central necrosis in the liver. In other words, obstruction as such may produce the clinical picture of acute yellow atrophy, so I should think it is much better called acute hepatic insufficiency. He has metastatic cancer in the liver, possibly it is primary in the common bile duct or gallbladder, and we must consider pressure on the duodenum possibly with ulcer in the ducts to produce this leucocytosis and the number of polymorphonuclears in the smear.

DR GEORGE W. HOLMES: The chest film confirms Dr. Jones's interpretation of the physical findings. There is a very high diaphragm and no evidence of fluid in the chest. The large amount of gas below the diaphragm may account for its position. I think the liver is definitely enlarged. The aorta is prominent. The heart shadow is not particularly large. It may be hidden in part by the high diaphragm and may be larger than it appears. The film taken of the urinary tract was blurred by motion. The edge of the liver is visible. It does not seem to be particularly low. The colon appears to be normal. The transverse portion is a little low for that type of man and there is a good deal of dullness above the colon.

DR JONES: Is there some pressure on the right side?

DR HOLMES: Yes, it looks as if there might be.

The stomach is displaced away from the liver to the left as though there was something pressing against it. Some of the films show the duodenal loop fairly well and that does not seem to be enlarged. A few cases of cancer of the pancreas show a wide loop. There is some evidence against the pancreatic tumor.

DR ARTHUR W. ALLEN: I saw this man in consultation in the medical ward and felt that the chance of being able to do anything for him surgically was extremely slight. He looked as if he could not live very long in spite of anything that could be done and it has been our experience that when we explore inoperable malignancy we have a very high mortality from the exploration. A considerable number of these patients will succumb to the disease following exploration before they can go home, and it suggested to me the possibility of utilizing a new diagnostic procedure, that is, new to this hospital, which Dr. Benedict was capable of performing and I suggested that he see the case with that in view. He did a peritoneoscopy with very satisfactory results.

DR EDWARD B. BENEDICT: It was due to Dr. Allen's trip to the west coast and his interest in the case that we did this peritoneoscopy. Dr. Ruddock of Los Angeles has done four hundred peritoneoscopies in the past few years with

very favorable results. A half inch incision is made, a very small trocar inserted and air blown into the peritoneal cavity. Then a larger trocar is used and a puncture made, after which the bistoury is removed and the observation telescope inserted. This is an instrument very much like the cystoscope except it has direct instead of right angle vision. It is equipped for biopsies. A special attachment can be introduced and a small biopsy taken. There is another part for withdrawing fluid. This cage-like affair is to keep the omentum away from the instrument and prevent its getting caught. A rubber tube with a light on the end can be introduced so that you can see the stomach and inflate it at the same time. In this patient I obtained a very good view of the liver in which I saw definite nodules throughout having the characteristic appearance of carcinoma probably metastatic.

CLINICAL DIAGNOSIS

Carcinoma involving the liver and bile ducts

DR. CHESTER M. JONES'S DIAGNOSES

Carcinoma of the bile ducts with metastases to the liver

Acute liver insufficiency

ANATOMIC DIAGNOSES

Carcinoma of the left upper bronchus with metastases to the liver and to the mediastinal, mesenteric and retroperitoneal lymph nodes.

Pleuritis, chronic fibrous left.

Pulmonary congestion

Bronchiopneumonia, right lower lobe

Peritonitis, acute fibrinous, localized.

Nephritis, chronic vascular

Operative scar, Partial amputation of the penis with hypospadias.

Operative wound, peritoneoscopy

Icterus.

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY The diagnostic problem in this case was a perfectly impossible one beyond the point of prophesying metastatic cancer in the liver. The only man who could possibly have made the diagnosis of the primary lesion was Dr. Holmes and he has failed us.

We found a primary cancer of the bronchus to the left upper lobe of the lung, with approximately five kilograms of metastases to the liver. It is a very great exception, as Dr. Jones pointed out that metastases to the liver produce jaundice. There were a couple of lymph nodes noted in close contact with the bile ducts which might have pressed on them but we have no particular reason to suppose that this was the case. The metastases were so extensive that he had vir-

tually no liver tissue left so that I feel the jaundice was due to hepatic insufficiency. However, the other general rule as regards metastatic disease of the liver held. He had no evidence of portal obstruction and his spleen weighed only 120 grams, not the slightest degree of enlargement.

DR. HOLMES May I say a word in retrospect?

I explained the high position of the diaphragm as being due to gas below it. It was probably due to the inability of the lung to expand. I should have considered that. Then this area which probably represents infiltration around the cancer, I thought was due to high diaphragm and partial collapse of the lung. It is perfectly easy to interpret it either way.

CASE 22112

PRESENTATION OF CASE

A fifty six year old colored housewife was admitted complaining of painful micturition and urinary frequency.

For fifteen years before entry the patient had nocturia of two to four times and diurnal frequency of every two to three hours. Two months prior to admission she began to have aching pain across the small of the back, slightly more on the left side and radiating into the left groin. At the same time there was some increase in her urinary frequency and occasional occurrence of pain with the passage of urine. During the succeeding weeks she complained vaguely of having sensations of heaviness of the head and recurrent hammering in the ears. She had spells during which she felt quite cold with occasional rigor and other times when she felt unbearably warm. Three weeks before entry she had a sudden dizzy spell and fell. Since that time she felt rather weak and short of breath but had only been confined to bed for six days prior to entry. Her appetite remained excellent. During the week preceding her admission she rapidly developed complete deafness and the hammering, previously described disappeared abruptly. For five days she appeared to drag her left leg and two days before entering the hospital she began to raise some thick sputum. Her temperature at that time was 101°.

She had been married fifteen years and had no pregnancies. During a previous marriage she had one child who died shortly after birth. The menopause occurred two years before entry. An abdominal operation had been done at the age of twenty. Three or four years before entry she had received injections into her buttock as treatment for a "blood disease." She had had frequent colds and sore throats up to one year before admission.

Physical examination showed an acutely ill

dyspneic colored woman lying flat in bed. The skin was hot and dry and the mucous membranes were pallid. The left ear drum was scarred, the right negative. The heart was slightly enlarged to the left. The sounds had a rough harsh quality and the rhythm was regular. No murmurs were audible. P_2 was accentuated. The blood pressure was 180/110. Dullness was elicited over both lung bases posteriorly and the breath sounds in this region were diminished in intensity. Over the remainder of the chest, except at the apices posteriorly, many constant, coarse and fine moist râles were heard. The liver edge was three fingerbreadths beneath the costal margin. The abdomen was greatly distended but no evidence of fluid was found. Ankle jerks were not obtained. Knee jerks were present and symmetrical. No plantar reflex was obtained on the left side, the right showed hallux deviation downward.

The temperature was 103° , the pulse 130. The respirations were 60.

Examination of the urine showed a specific gravity of 1.012 and a trace of albumin. The sediment contained many white blood cells but was otherwise negative. The blood showed a red cell count of 4,900,000, with a hemoglobin of 70 per cent. The white cell count was 6,600, 78 per cent polymorphonuclears, 15 per cent lymphocytes, and 7 monocytes. Several stool examinations were negative. A lumbar puncture showed an initial pressure of 150 millimeters. No cells were found. The alcohol and ammonium sulphate tests were negative. The nonprotein nitrogen of the blood was 35 milligrams per cent. The plasma protein was 5.4 grams per cent. The chlorides were equivalent to 93 cubic centimeters N/10 sodium chloride.

An x-ray showed fine mottling of both lung fields with an area of homogeneous dullness in the left lower lung field. There were multiple areas of calcification in the left hilus and tracheobronchial angle. The heart was not remarkable.

The patient ran a rapid downhill course with her temperature fluctuating between 102° and 106° . She soon went into coma and died on the fourth hospital day.

DIFFERENTIAL DIAGNOSIS

DR JOHN W. CASS. The history is that of a fifty-six year old colored housewife with the chief complaint of painful micturition and urinary frequency of many years' duration.

The past history consists chiefly of the facts that she had been married fifteen years with no pregnancies, that she had a child by her previous marriage that died shortly after birth and that three or four years prior to admission she had received injections for a blood disease. She had also been subject to chronic colds and sore throats up to one year prior

to admission. There is no mention of hemoptysis or of contact with tuberculosis. The history of injections for blood disease definitely suggests syphilis.

The chief complaint in the present illness is evidently of about fifteen years' duration, consisting chiefly of nocturia and frequency. These symptoms are unchanged until two months before entering the hospital at which time she began to complain of aching and pain across the small of her back which was more marked on the left side with radiation into the left groin. With these symptoms there was an increase in frequency and occasional pain on voiding. These statements suggest that there was a progression in her genitourinary pathology and that there was possibly localization of the process in the left kidney with a suggestion of obstruction to the left ureter.

Shortly before admission she complained of heaviness of the head and recurrent hammering of the ears. Such symptoms are usually on a hypertensive basis but might be due to an intracranial aneurysm or a brain tumor. Next in sequence were episodes of chilliness, rigor and warmth, these probably denoting a general reaction to infection which in this instance seems to be in the genitourinary tract and most likely localized to the left kidney. Finally, three weeks prior to entry, she had a sudden dizzy spell and fell. There is no history of resulting paralysis but the episode certainly suggests a vascular accident. Weakness followed this accident, with shortness of breath, and she was confined to bed for six days before coming to the hospital. It is stated that her appetite remained excellent and that during this period she had developed complete deafness with disappearance of the hammering sensation. This sudden complete deafness with clearing of the hammering is confusing and all one can say is that there must have been a central lesion causing this deafness and that the situation was in some way related to the suggestive vascular accident. It is also stated that she appeared to drag her left leg. This is further evidence in favor of an intracranial hemorrhage.

Just prior to entering the hospital she began to raise thick sputum and the temperature rose to 101° . There is no history of the amount or type of sputum raised and we would like to know if it was foul or contained blood. The history as given does not necessarily suggest a terminal pneumonia and we may be dealing with a long-standing pulmonary process such as bronchiectasis or tuberculosis.

On physical examination the essential points consist of the following. The patient was acutely ill. She was dyspneic, although lying flat in bed which suggests that the dyspnea was on a pulmonary rather than a circulatory basis. The left ear drum was scarred, the right negative. These findings are of no help in trying to ex-

plain the sudden bilateral deafness. The heart was slightly enlarged to the left, the sounds were of harsh quality the rhythm was regular and there were no murmurs. P was accentuated. The blood pressure was 180/110. I would expect that if this hypertension had been of long duration, we should have a larger heart. The accentuated pulmonary second sound indicates that the intrapulmonary pressure was proportionately greater than that of the general circulation. There is nothing to suggest heart failure in this examination. The chest examination reveals an extensive process with dullness at both bases and many fine moist rales throughout the remainder of the chest. This description could fit a diffuse bronchial pneumonia, diffuse capillary bronchiectasis or tuberculosis alone or combined with a terminal bronchial pneumonia. The liver edge was three fingers below the costal margin. This suggests an enlargement of the liver but we cannot be sure of this because there is no mention of the position of the upper border of the organ. The abdomen was distended. There was no evidence of fluid. The ankle jerks were not obtained. The knee jerks were present with no plantar response on the left but a positive Babinski reflex on the right. I cannot put these findings together and they are ones that are often noted on routine examinations in a person in a stupor and may not in this situation be of great importance although as given they suggest an intracranial lesion. There is no mention of edema or clubbing of the extremities. The absence of edema helps again to rule out congestive failure or chronic kidney disease with renal failure. The absence of clubbing is a help in ruling out chronic nonpulmonary disease as clubbing is more common in diffuse nontuberculous infections of the lung than it is in pulmonary tuberculosis, although of course clubbing does occur in pulmonary tuberculosis.

In the laboratory findings we note that the urine has a specific gravity of 1.012 with a trace of albumin and many white blood cells in the sediment. A specific gravity of 1.012 is low, particularly as it is suggested that the patient was dehydrated. There is no mention of casts in the urine and I should feel that this urine examination was more in favor of infection than chronic nephritis. The red cell count was 4,900,000 with a hemoglobin of 70 per cent. These findings again are against a chronic nephritis. The white cell count is 6,600 with 78 per cent polymorphonuclears. This is a rather low white count for an ordinary bronchopneumonia but it is consistent with tuberculosis or an atypical pneumonia such as might merely be a terminal event in a chronic nontuberculous pulmonary infection. The stools were negative. The spinal fluid findings as given are normal. There is no mention of a Wassermann reaction. The nonprotein nitrogen of the blood is nor-

mal and it seems that we can definitely rule out a chronic nephritis as a cause of the hypertension and genitourinary complaints. The plasma protein of 5.4 is within normal limits. The chlorides are a bit low but are compatible with a febrile disease. There is no mention of a blood Hinton examination or of examination of the sputum.

The x rays of the chest show fine mottling in both lung fields with dullness in the left lower lung field and multiple areas of calcification at the left hilus. The heart is not enlarged. The x ray finding of a heart of normal size bears out the physical examination and the assumption that we are not dealing with a long standing hypertension and congestive failure. The pathology described in the lungs is consistent with miliary tuberculosis for we know that the calcification at the hilus denotes at least an active infection in the past. The x ray description can also denote a diffuse capillary bronchiectasis or a pneumoconiosis.

It is stated that the patient died in coma on the fourth day after hospital admission and that she ran a fluctuant temperature between 102° and 106°. The findings suggest that the patient had had a long standing genitourinary infection and that she had had syphilis and tuberculosis. The hypertension could not have been of many years standing and I am inclined to feel that it did not contribute to her terminal disease. The terminal event was an acute infection, which probably included both the lungs and the genitourinary tract. It would be necessary to have an examination of the sputum for definite diagnosis. The suggestive vascular accident I am inclined to put on a syphilitic rather than a hypertensive basis, and she may have an intracranial aneurysm.

CLINICAL DIAGNOSES

Hypertensive and arteriosclerotic heart disease
Bronchopneumonia
Pyelonephritis
Cerebral thrombosis

DR. JOHN W. CASS'S DIAGNOSES

Miliary tuberculosis
Tuberculosis of the genitourinary tract
Syphilis
Hypertension without marked cardiovascular involvement

ANATOMIC DIAGNOSES

Miliary tuberculosis involving the lungs, pericardium, spleen, kidneys, bladder and meninges
Pott's disease fifth lumbar vertebra with right psoas abscess
Pleuritis, chronic fibrous, right

Ulcers of the cecum
Tuberculous adenitis, bronchial, healed?
Arteriosclerosis, slight, aortic
Fatty degeneration of the liver
Cholesterosis of the gallbladder
Peritonitis, chronic fibrous, focal
Nephritis, chronic vascular
Cystitis, acute
Leiomyomata uteri
Salpingo-oophoritis, chronic, left
Operative scar Right salpingo-oophorectomy

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY The autopsy on this patient showed a widespread miliary tuberculosis involving nearly every organ of the body. In such cases it is always interesting to attempt to trace the progress of the infection. Evidences of old tuberculosis were found in the form of small calcified areas in the bronchial glands and also of a puckered and slightly fibrous apex of the right lung. There was no sign of activity, however, in either of these lesions and it seemed improbable that an acute miliary tuberculosis could have arisen from them. The clinical history suggested strongly a chronic cystitis and less definitely a renal lesion. A chronic cystitis was demonstrated but there was

very little evidence to suggest that this was tuberculous, and although the kidneys were fairly extensively involved in the acute miliary process no suggestion of a chronic renal lesion could be demonstrated. It was not until the usual routine incision into the psoas muscles, without which no autopsy should be considered complete, that a lead developed. The right psoas and iliacus muscles showed a central fistulous tract containing thick greenish pus which could be traced backward to the anterior surface of the fifth lumbar vertebra. The anterior surface of the body of this vertebra was irregular and showed several small areas of softening. I think it is probable that this was the focus from which the miliary process developed. The only other possible focus was in the cecum, where a few small ulcers were formed. These, however, appeared to be acute terminal lesions only.

Examination of the brain showed a few small but definite tubercles in the pia arachnoid. There was no evidence of a vascular accident, and the shifting character of the symptoms referable to the cranial nerves is a not uncommon finding in tuberculous meningitis. It must be admitted, however, that that diagnosis could not reasonably have been made on the basis of the spinal fluid findings.

SURGICAL OPERATION FOR HIGH BLOOD PRESSURE

ALL recent therapeutic triumphs both in medicine and in surgery have been with rare exceptions, made possible through painstaking experimental and clinical studies on the nature of the diseases in question. Thus physiological and morphological studies of the autonomic nervous system and of the peripheral vascular system have opened up new possibilities in the therapeutic approach to diseases of these systems.

In recent years vigorous attempts have been made to influence arterial hypertension through surgical measures. The following premises have been or may be, proposed in favor of the surgical treatment of hypertension. (1) There is an increased secretion of adrenalin in hypertension. (2) Hypertension develops as a result of a primary pathology in the kidney and is precipitated through afferent nervous impulses from this organ. (3) In hypertensive patients there is a hyperactivity and an increased tonus of the vasomotor centers with resulting increased

motor nerve impulses and exaggerated pressor responses. (4) Even if the vasomotor tonus is not increased, surgical reduction of the normal tonus is desirable in view of the fact that in hypertension the vascular system is hyper-sensitive to normal nervous and chemical stimuli. (5) The elevated arteriolar pressure represents an effect of wear and tear, hence reduction of pressure is beneficial *per se*.

It should be pointed out, however that (1) Except in rare cases there is no evidence that increased secretion of adrenalin plays an etiological role. (2) Similarly evidence is lacking in support of the renal origin of "primary" (essential) hypertension, and surgical renal denervation actually fails to influence hypertension. (3) Some recent evidence suggests that the vasomotor tonus is not increased in hypertension. (4) If the normal vasomotor tonus could be diminished diffusely without affecting the emergency bodily functions essential for homeostasis, this would be quite beneficial. The decrease of vasomotor impulses within one region of the body on the other hand, may well have a deleterious effect on the function of vital organs in which the constricted state of the arterioles persists unaltered, and in which, as a result of decreased blood pressure, a sub-optimal circulation has developed. (5) It is also pertinent to recall that in animals even after complete exclusion of sympathetic control of the blood vessels the blood pressure is about normal.

Thus the "theoretical" indications for surgical interference are not so simple or so obvious as is believed by some. In spite of this, section of the splanchnic nerves, direct denervation of the suprarenal glands, suprarenalec-tomy, denervation of the kidney and spinal nerve root resection either alone or in various combinations, have been practiced and advocated by some as beneficial in arterial hypertension. It should be recalled that when these procedures were first introduced it was stated by the proponents that surgery might be justifiably applied in malignant hypertension in view of the fact that this condition is inevitably fatal. In the very clinic where surgery was proposed subsequent experience has shown that surgery does not alter the course of malignant hypertension. Nevertheless, later surgery was applied in benign hypertension a condition often compatible with longevity and characterized by marked, unexpected and irregular fluctuations. Soon thereafter several favorable reports claimed that benefit had been derived by the patients operated on. Can one judge the effects of these operations from relatively few cases, observed for only a relatively short period? Moreover, does the alleged symptomatic improvement justify such drastic surgical interference?

In the case of arterial hypertension, therapeutic proof is at best difficult. The value of these surgical procedures certainly cannot be considered established as yet. One wonders whether more experimental work and less "surgical trial" will not ultimately result in more definite therapeutic progress in this important condition.

AN ELECTRIC STARTER FOR THE HEART

NEWSPAPERS have recently dealt with accounts of a needle designed to carry electric stimuli to hearts that have stopped beating. They tell us it is to be inserted "in the exact spot of the natural pacemaker" and that it will deliver artificial stimuli at the proper rate and voltage to maintain cardiac function until the heart can again take up its work. A Dr Hyman was reported as having used it in seven cases, with "good results" in two.

The preciousness of human life in times of peace makes such announcements as this of great interest to all. A heart that has stopped beating must carry with it an overwhelming association with death. To start such a heart again, even in only two cases out of seven, is dramatic medicine. We must hopefully wait for further experience and confirmation before we can compare this electric starter with such procedures as the intra-ventricular injection of epinephrin. Even the bottle of smelling-salts has been known to do the same thing—if one is to believe his five senses.

In the meantime we may speculate upon emotions which the announcement of the electric starter might evoke in the various kindred fields of medical science. The anatomist will quickly visualize the precision with which the "exact spot of the natural pacemaker" must be located, the first year student will readily find the voltage of the proper electric stimulus in his physiology notebook, the hospital administrator will expect to be told how many starters will be needed to bring his equipment up to date, the interne will count the lives he might have saved during the past year, the clinician will make a note of another instrument without which he may become hopelessly out of date. The most disinterested and unconcerned observer of them all will be the medical examiner.

HEART DISEASE WITH PREGNANCY

Though in New England only one out of seventy five or one hundred pregnant women has a chronic, seriously damaged heart, at least 15 per cent of all maternal deaths in pregnancy and puerperium are due to heart disease. The importance of this small group of cardios is obscured not only by their rarity, but because they may die of heart failure undelivered or they may be transferred from an obstetrical ward or hospital to a medical ward or hospital following delivery and die later of heart failure and thus may not appear in obstetrical mortality tables. Heart disease, however, is in reality one of the major causes of deaths in pregnancy.

What do we mean by heart disease complicating pregnancy? Many women complain of moderate sensations of breathlessness and show on examination a rapid heart rate and disturbingly loud systolic murmurs. Fortunately we can dismiss these minor complaints and indefinite findings. It is a reassuring fact that with pregnancy no woman develops heart failure or dies of heart disease who does not show one of two definite physical signs of heart disease, namely (1) a diastolic murmur, or (2) a definite enlargement of the heart. All generalities in medicine have some exceptions. Exceptions to the above rule are exceedingly rare.

The converse of the above rule is equally important. Any woman who has, first a diastolic murmur, secondly an enlargement of the heart may develop heart failure in pregnancy at any time and may die. These facts are both reassuring to an obstetrician and at the same time, clearly point to a responsibility. The obstetrician does not need to bother with effort tests, electrocardiograms, roentgenographic studies or elaborate history taking in an attempt to deter-

A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

ne obscure heart defects. He need not be described by complaints of breathlessness, palpitation, pain in the region of the heart, fainting, sensations of weakness on exertion. But he must be able to auscult accurately and he must be able to detect an enlarged heart.

Any one can learn to hear a diastolic murmur, but it is as difficult to learn to recognize the mitral diastolic murmur accurately as it is to learn to do an adequate pelvic examination and much harder than it is to learn to count the fetal heart. Close to 80 per cent of the women who die because of heart disease with pregnancy have for their only reliable sign of disease before pregnancy a mitral diastolic murmur. Any dramatic histories could be given of women who were considered perfectly sound until they developed heart failure during the last trimester of pregnancy because of an undiscovered mitral stenosis. Among five hundred consecutive women with heart disease complicating pregnancy at the Boston Lying-in Hospital in 14 cases a mitral diastolic murmur was the physical sign that determined the diagnosis. In thirteen cases, an aortic diastolic murmur, in twenty-four cases, both aortic and mitral diastolic murmur. In the majority of the remaining sixty-nine cases, the diagnosis of heart disease depended on determining an enlargement of the heart.

Of these five hundred cases, thirty-two mothers died (the mortality rate was then 6.4 per cent).

Clearly, we should like to be able to tell before pregnancy or early in pregnancy the 93 per cent of cardiacs who will survive from the 7 per cent who will die if they are allowed to go on. The desire to accomplish this is so strong that we are apt to be led to follow more or less ingenious rules for sorting them out easily on a basis of response to effort tests. Such methods are not appropriate. We should always remember the working rule that any cardiac, as described above, may develop heart failure and that no patient who is not a cardiac, as described, will develop heart failure.

Statistics show, however, that (1) cardiacs who have developed auricular fibrillation have approximately a 50 per cent maternal death rate. Only three per cent of the cardiacs have auricular fibrillation, (2) cardiacs who have already developed heart failure when first seen—who have a clear history of congestive heart failure have approximately a 25 per cent death rate. Clearly, it is not advisable for such patients to attempt pregnancy. Analysis of the fatal cases shows that if these two groups of women who obviously should not attempt to bear children had not become pregnant, the remainder would face only a small death rate. Further refinements in determining the risk in individual cases can be made. But they are

too long to be described here. One rule can readily be remembered: heart failure occurs twice as often in women over thirty-five as in women under thirty-five. Women with heart disease then would do well to have their pregnancies before they are thirty-five.

The most important factor in the prognosis of women with heart disease complicating pregnancy is suggested by the following facts: in the first two hundred and fifty consecutive cardiacs delivered at the Boston Lying-in Hospital, the maternal death rate was 7.6 per cent. In the third and last two hundred and fifty consecutive cardiacs, the death rate was 2.8 per cent. (It is also impressive to note that approximately one-half the fatal cases were not followed carefully through pregnancy at the hospital, but came to the hospital already in a dangerously sick condition because of their hearts.) Proper treatment of a cardiac patient improves the chances of avoiding death at least four times.

Analysis of fatal cases shows that three quarters of the maternal deaths among cardiacs are due to heart failure and that such heart failure should be regarded as preventable by (1) proper advice to cardiacs who are unfit to stand pregnancy, (2) proper control of those who are fit. The majority of the remaining approximately 25 per cent of the maternal deaths among cardiacs are due to embolism or to bacterial endocarditis. We cannot hope that these fatalities can be effectively controlled.

An outline of the treatment of heart disease in pregnancy will appear in a later issue of this Journal.

MISCELLANY

MISBRANDED "RUBBING ALCOHOL"

The campaign against misbranded "rubbing alcohol", reported previously, was continued, netting 8,500 bottles during January. Despite the earlier actions against such mixtures, which proved to be water with varying proportions of isopropyl alcohol, a relatively new alcohol of doubtful safety, numerous lots were still found labeled with inferences that the "rubs" were none other than those made with grain alcohol as the principal ingredient.—*U S Dept of Agriculture*

DO CHILDREN HAVE TUBERCULOSIS?

Under the above title a pamphlet was prepared by the National Tuberculosis Association which has been reprinted by the Massachusetts Tuberculosis League.

This brochure contains accepted facts about tuberculosis which should be known by the laity.

Copies may be obtained on application to the Massachusetts Tuberculosis League, 1148 Little Building, Boston, Massachusetts.

HEALTH OFFICERS MONTHLY STATEMENT OF
VENEREAL DISEASES REPORTED IN THE
NEW ENGLAND STATES

DECEMBER, 1935

This statement is issued monthly for the information of health officers in order to furnish current data as to the prevalence of the venereal diseases. The following reports were received from State Health Officers. The figures are preliminary and subject to correction. It is hoped that this will stimulate more complete reporting of these diseases.

State	Syphilis		Gonorrhea	
	Cases	Monthly re- case	Cases	Monthly re- case
	ported	rates	ported	rates
	during	per	during	per
	month	10 000	month	10 000
	popula	tion	popula	tion
Connecticut	189	1.14	105	63
Maine	37	46	41	51
Massachusetts	437	1.01	530	1.02
New Hampshire	11	.23	3	.06
Rhode Island	126	1.79	38	.54
Vermont	16	.44	27	.70

Only cases of syphilis in the infectious stage are reported.

Treasury Department—Public Health Service

EPIGRAMS FROM BULLETIN OF THE NEW
YORK STATE MEDICAL SOCIETY

Arifhron said Without health life is not life.
Life is lifeless.

Charles H. Mayo said The public knows less of medicine than of any other science.

Automobile accident cases are frequently fracture conditions in which unskillful moving of the injured person is extremely hazardous. Doctors consider most operations on automobile accident cases as "postoperative" the automobile having been the first to operate.

There are more than two hundred recognized means with which human life is terminated. Heart disease today leads all of them in the toll it takes.

That there is no actual decline of mental power with increasing age is the announcement made by Dr. Irving Lorge of Columbia University. Dimming sight, slowing movements, dulled hearing is not a loss of mental power but merely a decrease in speed according to Dr. Lorge.

Cures for obesity are prohibited by law to be advertised in Canada.

Don't eat fruit that has not been washed.

RESUME OF COMMUNICABLE DISEASES IN
MASSACHUSETTS FOR JANUARY 1936

Disease	Jan., 1936	Jan. 1935	5 Yr Aver age*
Anterior Polymyositis	1	2	4
Chickenpox	1893	1899	1680
Diphtheria	55	35	165
Dog Bite	588	450	303
Epidemic Cerebrospinal Meningitis	17	4	7
German Measles	245	810	217
Gonorrhea	557	468	552
Lobar Pneumonia	1012	591	698
Measles	1629	1246	2400
Mumps	2101	302	694
Scarlet Fever	1303	774	1378
Syphilis	443	410	424
Tuberculosis, Pulmonary	331	281	310
Tuberculosis O F	42	27	38
Typhoid Fever	7	6	11
Undulant Fever	5	1	—
Whooping Cough	357	339	853

Based on the figures for the preceding 5 years

RARE DISEASES

Anterior polymyositis was reported from Attleboro 1

Diphtheria was reported from Boston 12, Bourne 1, Brockton 1, Chicopee 16, Fall River 3, Framingham 1, Gloucester 1, Lowell 8, Lynn 3, Malden, 1, New Bedford 2, Pittsfield 1, Salem 1, Tewksbury 3, West Springfield 1, total 55

Dysentery (bacillary) was reported from Danvers 5

Epidemic cerebrospinal meningitis was reported from Boston, 2, Bridgewater 8, Fitchburg, 1, Malden, 1, Northridge 1, Springfield, 1, Spencer 1, Webster 1, Worcester 1, total 17

Paratyphoid was reported from Haverhill 1

Pellogra was reported from Medford, 1.

Septic sore throat was reported from Amesbury 1, Belmont, 1, Boston 3, Chicopee 5, Easton, 3, Gardner 3, Lowell 1, Middleboro 1, Worcester 1, total 17

Tetanus was reported from Stoughton 1

Trachoma was reported from Haverhill 1, Malden 1, total 2

Trichinosis was reported from Arlington 1, Boston, 1, total 2.

Typhus fever was reported from Boston 1.

Undulant fever was reported from Brockton 1, Milford, 1, Milton 1, North Adams 1, Westfield 1, total 5

Diphtheria. The increase for the month over the 1935 record low level is explained by the reporting of 16 cases from Chicopee as against none the year previous and 12 from Boston as compared with 6 in 1935

Epidemic cerebrospinal meningitis. The increase

in reported epidemic cerebrospinal meningitis over last January is due for the most part to an outbreak of 8 cases to date at the Bridgewater State Farm

Dog Bite The reporting of dog bite continues high. There were, however, but 6 cases of canine rabies for the month as compared with 28 for last January.

Lobar pneumonia had its highest reported January incidence since 1929. This increase over last year's figure first became apparent in the spring of 1935.

Scarlet fever has maintained a level higher than the previous year since the fall of 1935.

Mumps had its highest reported January incidence in the history of the State.

The reported incidence of the anterior poliomyelitis, chickenpox, German measles, measles, and tuberculosis other forms, was not remarkable.

Pulmonary tuberculosis was somewhat higher than January of 1935, probably due in the most part to better case finding and reporting.

Typhoid fever was reported well within the five-year average. Three typhoid carriers have been discovered to date in connection with the investigation of these cases.

Undulant fever continues to be reported higher than last year with practically every case giving a history of using raw milk.

Whooping cough had its lowest reported January incidence since 1922.

AFFAIRS IN CONNECTICUT

John Bucciarelli, M.D., has been appointed health officer of New Canaan in place of M. J. Brooks, M.D., retired.

Michael D. Riordan, M.D., has been appointed health officer of Windham for a term of four years.

Reuben Rothblatt, M.D., has been appointed acting health officer of Willimantic during the absence of Nathan N. Spector, M.D.

Following the resignation of Leonard C. Greenburg, M.D., as health officer of New Haven, Clement F. Batelli, M.D., was appointed acting health officer. He in turn was replaced on December 16, 1935, by Joseph I. Linde, M.D., as health officer.

Clifford S. Pine, M.D., of Naugatuck has been appointed health officer of Beacon Falls for the unexpired term which ends in October, 1938.

At the last session of the State Legislature of Connecticut the following act was passed: "The state department of health is authorized to make investigations concerning cancer, the prevention and treatment thereof, and the mortality therefrom, and to take such action as it may deem will assist in bringing about a reduction in the mortality due thereto." This act was recommended to the legislature by the State Medical Society and the work of carrying on this study has been assigned to the Bureau of Preventable Diseases of the State Department of Health. Mr. Herbert F. Hirsche, C.P.H.

has been appointed as research statistician to aid in the study of the cancer problem in Connecticut.

At this same session of the State Legislature a law was passed known as the Uniform Narcotic Act. Under this act the regulation of narcotics in Connecticut becomes uniform with Federal government control and with control in many other States. The State Department of Health is delegated certain responsibilities of enforcement under this act, these being placed under the Bureau of Preventable Diseases.

Dr. Stanley H. Osborn, Health Commissioner of Connecticut, has predicted that over \$150,000 of Federal funds for public health work, maternal and child health service, and aid for crippled children will be made available for Connecticut in the immediate future. It is expected that the total will include \$79,000 for public health work and about \$38,000 each for crippled children and for maternal and child health services.

With this money Dr. Osborn will be obliged to secure fifteen to twenty additional employees, and thus will increase the number of city and town health departments with a fulltime medical officer in charge of each. It is hoped that this will permit studies of occupational disease control and a broad study of cancer control.

Dr. Benjamin G. Horning, a member of the State Department of Health, will be placed in charge of the drive for so-called fulltime health departments in cities and towns. Not more than eight towns and cities in the State have health departments with fulltime health officers in charge. The Federal allotments for this purpose will decrease at the rate of five per cent a year, thus permitting a gradual assumption of the financial burden by the cities and towns. Under the Social Security Law no state can secure Federal money under any of the titles of the act until it has submitted an approved plan for the particular project. This state has already submitted its maternal and child health plan to the Children's Bureau of the Labor Department.

FLAT RATE FOR HOSPITAL AND PHYSICIAN IN OBSTETRICAL CASES

Out of 199 births at Windham Community Hospital, Willimantic, during 1935, 150 were under the hospital's so-called "middle rate maternity plan." This plan provided both hospitalization and physician's care for a total sum of \$65. The only requirement made is that the attending obstetrician shall be a member of the hospital staff. In such a case \$30 is paid when the patient enters the hospital and \$35 on discharge of mother and baby. This flat rate includes prenatal care, hospital care, and postpartum care even for a short period after mother and baby have gone home.

The maternal mortality for this hospital for 1935 was zero, a record the hospital has maintained since its opening in 1933. The hospital collected 100

per cent of its hills for private room care in obstetrical cases and 93.1 per cent of its hills for middle rate care.

HARTFORD HAS NEW HIGH MORTALITY RATE IN HEART DISEASE AND CANCER

Five hundred and thirteen deaths from heart disease in Hartford for 1935 is the highest ever recorded in the history of the city. This gives a rate of 238 per 100,000 population. The previous year there were 497 such deaths. Cancer claimed 235 deaths in Hartford during 1935 a rate of 1.6 per 100,000. The previous peak was reached in 1931 with 119 deaths. The total number of deaths from all causes was 1877.

During January 1936 there were 219 deaths in Hartford a reduction of two over the previous January. Births increased during this month from 302 to 320 and marriages declined from fifty-six to nineteen as compared with the same month last year. Heart disease leads for January, 1936 as a cause of death, there being a total of fifty-three as compared with fifty one year ago.

The Hartford Board of Health has resumed its monthly bulletins discontinued in 1923. The reports are to be sent to physicians and other interested persons, and to public health organizations here and throughout the country in accordance with the practice of health boards of exchanging reports for purposes of comparing methods of public health procedure and results obtained.

MODERN HEALTH SERVICE FOR A CITY OF 200,000 POPULATION*

A health program of modern health service for a city of 200,000 population was presented to the Hartford Medical Society on February 17, 1936 by Dr. Wilson G. Smillie, Professor of Public Health Administration of Harvard University School of Public Health.

In his opening remarks Dr. Smillie emphasized in how many ways the modern municipal health department departed from the plan of our forefathers in which the health board settled the disputes engendered by one's neighbor's chickens, waged war against rats, supervised garbage disposal, inspected plumbing, and in general acted as a court of last resort in many controversial matters now considered far afield from public health administration. Dr. Smillie went on to say that the state is the sovereign power in our government and the municipality has only such powers as are granted by the state. No exact criteria for public health administration may be determined for all types of cities in the United States because there exists such a diversity of population as well as of problems. Thus it is not possible to promulgate a uniform standard plan which would be suitable for all cities.

Dr. Smillie then explained that the State De-

partment of Health acts as a supervisor and an advisor and in addition does carry on certain direct activities which can be accomplished much better if administered on a large scale. The manufacture and distribution of standard biological products and the hospitalization of the tuberculous are examples of direct state service.

In outlining the functions of a health department for a city of 200,000 population the speaker developed the municipal health department as a primary unit with the following functions:

1. Recording and analysis of vital statistics
2. Control of communicable disease.
3. Providing epidemiological service, especially in tuberculosis and the venereal diseases.
4. Stimulating community immunization such as smallpox vaccination and diphtheria immunization
5. Providing readily available to all physicians, biological products for the prevention and cure of communicable diseases.
6. Providing an expert consultation service to all physicians in case of communicable disease including the less common and the more difficult of differential diagnoses.
7. Controlling tuberculosis by case finding, clinic service, field nursing and institutional care.
8. Providing for venereal disease control by clinic service and case finding.
9. Developing child hygiene by prenatal and maternity service and postnatal care with special attention to infant hygiene, preschool hygiene and school hygiene.
10. Control of sanitation.
11. Health education.

The problem concerning proper administration of the health department immunization service was discussed. Should the health department provide free immunization against diphtheria, smallpox and typhoid fever to all who request this service or should this service be given only to those who are too poor to pay for the services of a private physician?

The answer is a simple one. We may use diphtheria immunization as an example. The private physician is under obligation to protect the health of the children of those families under his care, but has no direct community responsibility. The health officer is obligated to protect his community from invasion by communicable disease. If 35 per cent to 50 per cent of preschool children of the community are continuously immunized against diphtheria, the community is protected against the spread of diphtheria. Thus the health officer must carry out a continuous immunization program so that at least 35 per cent of all babies are immunized before they reach school age in order to accomplish this purpose. The children of those parents who are too poor to pay for immunization service must be protected free of charge. Those children whose parents can pay for the service should be im-

* Original report edited by Dr. Smillie.

munized by private physicians. The health department nurses and other personnel should urge all persons to go to their own physicians for immunization. If this method does not secure an immunization of at least 35 per cent of the children before the age of two years, the health department has no other recourse than protection of the community by free public clinics.

In discussing the function of child hygiene it is emphasized that in this country, up to the present time, prenatal, maternity and postnatal services have not been considered as governmental functions. Rather, the physician delivering the mother or the hospital providing this service have been responsible, in great part, for this activity. Private nursing agencies have carried a part of this particular burden in some cities.

Infant hygiene is a development of recent years and has met a very real need. The clinical phases of infant hygiene are not a basic health department function, but rest with the private physician. Infant hygiene clinics should, however, be carried on for the indigent under health department auspices and staffed by local physicians who are paid for their services by the municipality.

School hygiene has been found to work out best if administered as a health department function. This work should include school medical examinations, nursing service, health education, nutritional service and dental hygiene. In general, the correction of defects is not a health department function. Each physical defect should be called to the attention of the parent, who should be advised to consult the family physician or dentist concerning the matter. It should be emphasized that school health service belongs in a well rounded health department and not to the department of education.

An example of local New England color was introduced by Dr. Smillie when he reminded his audience that the first health department in our country was established in Boston in 1799 and the first chairman of this board was the renowned Paul Revere.

There are several other functions in which a municipal health department should be directly interested, viz.,

- 1 Control of smoke
- 2 Prevention of accidents
- 3 Housing supervision to prevent overcrowding
(The incidence of tuberculosis and cerebrospinal meningitis is directly influenced by overcrowding)
- 4 Supervision of water supplies as to adequacy, safety and purity
- 5 Supervision of milk supply, giving due consideration to the adequacy, purity and safety of the municipal milk supply
- 6 A public health laboratory

Dr. Smillie then outlined the organization of a successful health department as follows:

I A Board of Health comprising three to five members and no more. This Board should be appointed by the Mayor, approved by the City Council, the terms of office to be rotating, and the functions to be advisory, not executive. In some cities by special provisions of the charter, this Board has quasi-judicial functions.

II A Health Officer, full time, and chosen by the Board of Health. He should be preferably a physician and should be trained and experienced in the special field of public health. Medical school training is not sufficient to fit the applicant for an administrative position in public health. The minimum requirements of a Health Officer for a community of 50,000 or over, as set forth by the State Health Officers' Association are as follows:

- 1 Proper training in vital statistics
- 2 Some knowledge of general and theoretical epidemiology
- 3 Familiarity with the historical background of public health administration
- 4 Sufficient knowledge of public health bacteriology to carry out customary procedures
- 5 General knowledge of water purification and sewage disposal
- 6 General knowledge of the spread of disease through food
- 7 Detailed knowledge concerning immunization against communicable diseases
- 8 Epidemiology and clinical knowledge, including therapeutic, of tuberculosis
- 9 Epidemiology and clinical knowledge, with special training in the therapy of venereal diseases
- 10 Familiarity with the whole field of nutrition
- 11 Training in health education
- 12 Training in mental hygiene.
- 13 General knowledge of government organization and a special knowledge of public health laws
- 14 Knowledge of social problems

The key person of the whole personnel is the health officer. He must be especially well trained and well qualified for his work.

III A Public Health Nurse as supervisor with assistants are required, usually twenty to thirty.

IV A Director of Child Hygiene, who should be a physician.

V Director of Sanitation and his assistants.

VI A Director of the Laboratory and his assistants.

VII Medical, Dental and Clinical Aides on a part-time basis.

In closing Dr. Smillie referred to the per capita cost for an adequate public health service for a community of 200,000 people. He said that \$100 per capita was the approximate sum now being spent by efficient municipal health departments, exclusive of hospitalization costs for tuberculosis.

and communicable disease Based on a population of 175 000 a city such as Hartford would anticipate that the required public health budget for one year would be about \$175 000 Exact budgets cannot be recommended for any given city of course, since part of the burden may be carried quite effectively by voluntary agencies at no direct cost to the public

CORRESPONDENCE

THE DANGER INHERENT IN SENATE BILL 394

Editor *New England Journal of Medicine*

In your *Journal* of February 27 there appeared a letter voicing opposition to Senate Bill 323 of the Massachusetts Legislature May I call the attention of every member of the medical profession, especially the Oculists to the fact that this bill has been with drawn and a more vicious and insulting bill Senate 394 has been substituted. (Hearing on this new bill March 19)

Senate 394 proposes that all Oculists come under the rules and regulations of the Board of Optometry As such they will have to follow the method (optometric) of examination prescribed by the Board—they will have to keep certain records—they will be prohibited to perform free examinations—they will be forced to charge a uniform fee If examination is made at the patient's bedside, reports of the prescribed glasses will have to be forwarded to the Board—and oculists will be prevented from dispensing glasses until they first pass an examination which licenses them as opticians (an examination from which optometrists are exempt)

There is no more relation between the Optometrist and the Optician than between Physician and Pharmacist. The former is a profession the latter a business. If the board actually wins control over the trade of dispensing glasses the oculist is directly affected. In a small community for example where an oculist, an optometrist and optician are located the action of the Board of Optometry would mean the elimination of the optician forcing the patient of the oculist to take his prescription to the optometrist—a situation which would eventually not be relished by the physician.

This bill should be defeated.

Very truly yours,

B EDWARD SACHE M.D

OFFICIAL ACTIONS OF THE BOARD OF REGISTRATION IN MEDICINE

State House, Boston

February 29 1936

Editor *New England Journal of Medicine*,

This is to inform you that at a meeting of the Board of Registration in Medicine held February 27 1936 It was voted to revoke the registration of Dr Russell B. Street, Conway Massachusetts, following Dr Street's admission to the Northampton State Hospital.

STEPHEN RUSHMORE, M.D., Secretary

AN INTERESTING ITEM OF MEDICAL HISTORY

March 2 1936

Editor *New England Journal of Medicine*,

The enclosed announcement, yellow and were with age was found by a patient of mine among some old records The quaintness of its style and the import of its message would doubtless interest *Journal* readers

It is noteworthy that, then as now a spirit of self-sacrifice and an absence of hope of pecuniary compensation prevailed in medical teaching

ROR J HERRINGTON M.D

Boston June 1 1811

Sir

In conformity with the opinion of the publick and especially of the fellows of the MASSACHUSETTS MEDICAL SOCIETY a medical school is now established in the town of Boston and has commenced its operations The general approbation of this new arrangement has surpassed the hopes of its most sanguine advocates the number of students attending the lectures having been about double that of any former period while the interest displayed in the prosecution of their studies and the satisfaction expressed on a review of them at their opportunities and acquisitions have been highly flattering and animating to the professors.

The course will be continued the ensuing winter on the following plan

ANATOMY AND PHYSIOLOGY	}	\$20
SURGERY AND MIDWIFERY		
CHEMISTRY AND MATERIA MEDICA		\$15
THEORY AND PRACTICE OF MEDICINE		\$15
CLINICAL MEDICINE		\$15

The lectures will commence on the first Wednesday in November and terminate on the first Wednesday in February

The students who attend the professor of Clinical Medicine will have an opportunity of seeing diseases and medical treatment in the hospital department of the Alms House

Those who attend the lectures on Anatomy may see the surgical practice of the same place, and such private operations, as circumstances will admit.

The valuable library founded by WARD NICHOLAS BOSTON ESQ will be open to the students. This library contains about seven hundred volumes, selected with great care relating to all the branches of medical science.

Other arrangements for the advantage of students which cannot with propriety be published will be made before the opening of the lectures.

The fee for attendance on the anatomical lectures has been reduced, in order that it might not exceed that established in other places. The professors avail themselves of this opportunity to remark, that in their arrangements for the medical school they have never been guided by the hope of pecuniary compensation. On the contrary they do not expect to receive any reward of this nature,

which will compensate for the sacrifice of private practice to their official duties in the anatomical branch, which, as is usual, is more fully attended than the others, the expenditures have actually exceeded the receipts, even independently of the cost of a valuable collection of preparations, and without estimating the labour of the professors. They are not discouraged under this state of things. They feel that circumstances have placed them, however unmeritedly, in a situation important to the interests of medical science in this part of the country and they are determined to fulfil the duties of it to the utmost of their ability so long as they receive the approbation of the respectable portion of the medical community of this state for the support of the faculty, and the exertions of the professors are equally necessary to the existence and success of an ample and efficient school of medicine in this section of the United States.

JOHN WARREN,
AARON DEXTER
JAMES JACKSON,
JOHN C WARREN,
JOHN GORHAM

The government of the University have determined that in future the degree of Doctor in Medicine shall be conferred on the same conditions that the degree of Bachelor of Medicine has hitherto been given. Candidates are required to have studied two years with some respectable practitioner, to have attended two of each of the courses of medical lectures, and then, at the end of the third year, they may present themselves for examination. The examination will be held in Boston, fourteen days subsequent to the termination of the winter courses.

Bachelors in Medicine of this University will be entitled to the degree of Doctor in Medicine.

TOTAL THYROIDECTOMY FOR HEART DISEASE

Editor, *New England Journal of Medicine*,

In the issue of your *Journal* of February 13 1936, appeared a summary of the investigations performed by Drs Clark, Means and Sprague on Total Thyroidectomy for Heart Disease.

Already two years ago, when the enthusiasm for the operation soared high, I could see that the rationale for the operation was irrational. In my paper published in the November 1934 issue of the *Canadian M A J* I said "the theory based on lowering the demands and keeping the function of the heart at its previous level is untenable". Therefore, in regard to the authors' sentence "The theory underlying this new practice was elemental in its simplicity", let me be permitted to say that it was simple but wrong.

Perusing the authors' paper I can see that my misgivings have proved well founded. In my letter published in the *J A M A* more than a year ago I said "When one speaks of selection of cases in a general way, it does not mean much. As I pointed out in my paper so far there is no scientific way of defining such a group of patients. The investiga-

tors must work out a strict definition of such a group before offering the operation for general use. Cachexia strumipriva which cripples the patient for the rest of his life must be the lesser evil in such cases. The selection of proper cardiac patients will be a difficult, if not an impossible, task."

In their paper the authors pointed out that all the twenty-one patients were very carefully studied and examined by many specialists, that the operations were performed by excellent surgeons. The authors used the frequent advice of Dr Blumgart. In spite of it, fifteen patients are already dead. In all fairness these fifteen cases should be thought of as wrongly chosen. In two out of the living six patients (cases 15, 18) the operation is considered by the authors not worthwhile, and in one (case 3) thyroid regeneration occurred. Therefore, the results may seem worthwhile in only three cases out of twenty-one (cases 13, 14, 16). However, in my opinion, these results are also meagre. For instance, in case 16, an old physician six months before entering the hospital suffered very severe precordial pains on walking or any marked exertion and was always promptly relieved by nitroglycerine. The physical examination was negative. There were never any symptoms of congestive failure. The metabolic rate was —17. After the operation he did not work for five months (June-November). Ten months later (the following September) he was seen and appeared to be very well, reporting only a little substernal aching on smoking or on walking any distance which was promptly relieved by nitroglycerine. He had been able to "carry on with his office practice steadily except for a three weeks' vacation". The history does not mention that he could not carry on with the office practice before operation, sometimes such work does not require great exertion. Why operate on such a person? Many such cases get along pretty well for years with nitroglycerine. Now he uses nitroglycerine and thyroid. He is myxedematous. One should not forget that, according to Kocher, the deterioration from myxedema progresses with the passing of time. In case 13 the patient after fifteen months showed a state of recurrence and after eighteen months a state of gross congestive failure. In case 14 the patient is myxedematous, uses thyroid, complains of easy fatigability. "He is looking for a job but has not yet found one." If these three patients that are still alive die in the near future, which is a probable possibility, no worthwhile cases would be left.

The authors give eleven well defined contraindications for the operation. Their only indication in favor presents, in my opinion, a generality. The authors also write, "It is significant that while we have not abandoned this procedure, with the large number of cardiac patients seen on the wards in the past six months, in no case have we felt sufficiently confident to recommend the operation." Of course, it is most significant. If the authors who are known specialists and authorities cannot select a suitable case among many who can? Why not face the facts? Why not discourage a procedure which for

three years has not met the expectations and involves tremendous risks and misery?

O. R. LOUEN, M.D.

485 Commonwealth Avenue
Boston, Mass.

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

535 North Dearborn Street, Chicago, Illinois

March 4, 1936

Editor *New England Journal of Medicine*

In addition to the articles enumerated in our letter of January 31 the following have been accepted:

Arlington Chemical Company

Arlico Protein Extracts

Mead Johnson & Co.

Mead's Oleum Percomorphum 50% (Percomorph Liver Oil 50% in Cod Liver Oil)

Mead's Oleum Percomorphum 50% (Percomorph Liver Oil 50% in Cod Liver Oil) in 10-drop (225 Gm.) Capsules

Mead's Cod Liver Oil Fortified with Percomorph Liver Oil

United States Standard Products Co.

Ample Solution Procaine with Epinephrine 1 cc

The Valentina Company

Solution Liver Extract—Valentine

Your sincerely

PAUL NICHOLAS LEECH, Secretary
Council on Pharmacy and Chemistry

RECENT DEATHS

PACKER—GEORGE WILLIAM PACKER, M.D., of 576 New Boston Road, with an office at 90 Queequechan Street, Fall River, Massachusetts, died suddenly at his home March 4, 1936.

Dr. Packer was born in Fall River and graduated from the College of Physicians and Surgeons of Boston, Massachusetts, in 1903. He joined the Massachusetts Medical Society in 1923 and in addition was a Fellow of the American Medical Association.

Dr. Packer was a member of the Elks and Order of St. George.

ELLIS—RALPH WARREN ELLIS, M.D., of 22 Howland Terrace, with an office at 574 Main Street, Worcester, Massachusetts, died at his home March 3, 1936.

Dr. Ellis was born in Worcester in 1891, the son of the late Dr. Dean S. Ellis and Mrs. Isabelle (Warner) Ellis. He was educated in the Worcester public schools, graduating therefrom in 1911 from Clark University. In 1914 and the Harvard Medical School in 1918. Fellowships in the Massachusetts Medical Society and the American Medical Association were acquired in 1919 after interne service at

the Worcester City Hospital where Dr. Ellis subsequently became a member of the staff.

Recognition of his standing is shown by his record of activities in the local medical societies and election to the position of Secretary of the Medical Section of the State Society in 1932.

He was a member of the Wesley Methodist Episcopal Church, the Quinsigamond Boat Club, the Y. M. C. A. and the Appalachian Mountain Club.

Dr. Ellis is survived by his mother, his widow, Mrs. Mary (Howard) Ellis, a son, Ralph W. Ellis, a daughter, Miss Virginia H. Ellis, a brother, Dean E. Ellis, of Bloomfield, N. J., and two sisters, Mrs. Leon E. Felton, of Worcester, and Mrs. Clifford A. Foster, of Westley.

BALDWIN—FREDERICK WILLIAM BALDWIN, M.D., of Danvers, Massachusetts, died at the Beverly Hospital March 7, 1936.

Born in Birmingham, Alabama, December 14, 1861, he graduated from the Harvard Medical School in 1886 and joined the Massachusetts Medical Society in 1893, serving for a time on the Council. Dr. Baldwin was a Fellow of the American Medical Association, held membership on the staff of the Beverly Hospital and was one of the founders of the Hunt Memorial Hospital of Danvers. He was formerly chairman of the Board of Health of his home town.

A sister, Mrs. Walter Page Weston, of Danvers, three nieces, Elizabeth Louise and Constance Weston, and a nephew, Stephen Weston, survive him.

OBITUARY

DR. CLARA E. GARY

FIRST VERMONT WOMAN TO ENTER MEDICAL PROFESSION

Dr. Clara Emerette Gary, for fifty years a practicing physician in Boston, died at her home, 418 Marlborough Street, on Saturday, February 15, after a year of failing health. She was born in Middlesex, Vermont, the daughter of Ephraim and Sarah (Robinson) Gary. When she was five years of age the family moved to Montpelier, where she graduated from the High School. After a year as a special student at Montpelier Seminary she entered Boston University School of Medicine in October, 1882, being the first Vermont woman to take up medicine as a profession. She received the degree of Doctor of Medicine in June, 1885, and was appointed Woman House Surgeon at the Boston Homoeopathic Hospital, the first woman to receive such an appointment in that hospital.

Dr. Gary was later House Surgeon at Boothby Private Hospital, Pharmacist in the Out-Patient Department at Boston Homoeopathic Hospital, and Lecturer in the School of Medicine at Boston University, 1888-1898. She was a pioneer in electrotherapy and took a special course at the Massachusetts Institute of Technology in 1896, with Professor Norton, gave a demonstration lecture on x-ray in Boston, the proceeds from it being donated to the Endowment Fund of Boston University School

of Medicine After further study in electrotherapeutics in this country she went to Europe for advanced courses, receiving a diploma in 1902, then visiting Vienna and London hospitals as observer Since 1900 her home and office had been at 416 Marlborough Street, Boston, her specialties being physiotherapy and the treatment of nervous diseases

In 1927 the University of Vermont conferred upon her the honorary degree of Doctor of Science

During the World War Dr Gary gave free medical aid to families of men in service, was a member of the War Service Committee of the Massachusetts Daughters of the American Revolution, and was New England Chairman of the Woman's Homoeopathic Base Hospital Unit She was a member of the Volunteer Medical Service Corps

She was formerly Vice-President of the American Institute of Homoeopathy and one of the organizers of the Institute Fraternity She held various offices in the National Society of Physical Therapeutics and the Massachusetts Surgical and Gynecological Society, and was a member of the Massachusetts Homoeopathic and Boston Homoeopathic Hospital Medical Societies and of the Alumni Association of Boston University School of Medicine

She was a member of the Daughters of Vermont and of the National Society Daughters of the American Revolution, Honorary Member and formerly Regent of Old Boston Chapter, D. A. R., and a member of various other organizations

She was the author of many medical papers and occasional poems

The late Frank E. H. Gary, a prominent Boston lawyer, was a brother

Burlal, with a brief service, was in the family lot in Montpelier, Vermont

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 on Thursday, March 19, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr Henry A. Christian, Physician in Chief, Hersey Professor of the Theory and Practice of Physics in the Harvard Medical School, will give a medical clinic To it are cordially invited practitioners and medical students

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12, staff rounds will be conducted by Dr Christian

UNITED STATES CIVIL SERVICE EXAMINATION

Associate Research Physiologist, \$3,200 a Year

Applications must be on file with the United States Civil Service Commission at Washington, D. C., not later than March 30, 1936

The United States Civil Service Commission announces an open competitive examination for the

position named above Vacancies in this position in the field and in positions requiring similar qualifications will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion The salary named above is subject to a deduction of 3½ per cent toward a retirement annuity

Present Vacancy—A vacancy exists at the present time in the Air Corps, Material Division, Wright Field, Dayton, Ohio

Duties—To establish, equip and operate a physiological and biochemical research laboratory to investigate all phases of the effects of flying on the human organism

Basis of Ratings — Competitors will not be required to report for examination at any place, but will be rated on their education and experience on a scale of 100, such ratings being based upon competitors' sworn statements in their applications and upon corroborative evidence

ANNOUNCEMENT OF EXAMINATION FOR APPOINTMENT AS ASSISTANT SURGEON (MEDICAL ONLY) IN THE REGULAR CORPS OF THE U. S. PUBLIC HEALTH SERVICE

An examination for entrance into the Regular Corps of the United States Public Health Service in the grade of Assistant Surgeon (medical only) is hereby announced to be held April 13, 1936 Applicants must not have passed their thirty-second birthday

The compensation of officers in the grade of Assistant Surgeon is \$3,158 per annum with dependents and \$2,699 per annum without dependents

Persons desiring permission to take this examination should make request to the Surgeon General, U. S. Public Health Service, Washington, D. C., for the necessary blanks and other information

W. F. DRAPER, Acting Surgeon General

INTERNATIONAL UNION AGAINST TUBERCULOSIS

PRESS NOTICE

The Xth Conference of the International Union against Tuberculosis (Secretary General Professor Fernand Bezançon) will meet in Lisbon, from September 7 to 10, 1936, under the chairmanship of Professor Lopo de Carvalho, President-Elect of the International Union The discussion will be limited to three main subjects Biological subject "Radiological aspects of the pulmonary hilum and their interpretation", opening report by Professor Lopo de Carvalho (Portugal), Clinical subject "Primary tuberculous infection in the adolescent and the adult", opening report by Dr Olaf Scheel (Norway), Social subject "The open case of tuberculosis in relation to family and domestic associates", opening report by Drs Ch. J. Chatfield (United States) and D. A. Powell (Great Britain) Ten speakers selected in advance from a list presented by the forty-four countries belonging to the Union have been designated

to open the discussion on each of the questions on the agenda¹

The Organization Committee of the Conference has prepared a very attractive program of receptions and excursions the latter will enable members of the Congress to visit the chief antituberculosis institutions as well as the most picturesque scenery in various parts of Portugal.

Members of the International Union are invited to take part in the Conference free of any contribution fee. They may forward their application either through the medium of their Government or their National Organization against Tuberculosis or directly to the Organizing Committee in Lisbon at the following address:

Organising Committee of the Xth Conference
of the International Union against Tuberculosis
Assistencia Nacional aos Tuberculosos
Avenida 24 de Julho Lisbon (Portugal)

Names may also be sent to the Headquarters of the Secretariate of the International Union against Tuberculosis, 66 Boulevard Saint Michel Paris (6ème)

Persons who are not members of the Union and who wish to take part as 'Members of the Conference must forward their applications, together with a contribution of 200 escudos (approximately 150 French francs) exclusively through the medium of

The National Tuberculosis Association
50 West 50th Street
New York City

Reductions on hotel prices and railway fares will be granted to Members of the Congress

All supplementary information may be obtained by applying to the International Union against Tuberculosis 66 Boulevard Saint Michel, Paris (6)

***Co-Reporteurs**

Biological subject Aust. la.—Dr Ludwig Hoffbauer Czechoslovakia—D. A. Hoffmann, France—Professor Emile Sargent Drs. L. Delerm and P. Cottenot, Germany—Professor Dr. H. Kleinschmidt, Great Britain—Dr W. T. Munro, Italy—Professors Ariadde Bosc, Lithuania—Dr A. Jacana, Poland—Professors J. Kowalewski, United States—Dr H. C. Swaney

Clinical subject France—Dr J. Troulser, Germany—D. Nadaker, Great Britain—Dr L. E. T. Burrell, Hungary—Dr Géza Gell, Roumania—Drs S. Imreescu and M. Nasta, Spain—Professor L. Bayas and Dr Tapia, Sweden—Dr H. Brander, Switzerland—Robert E. Plunkett, Yugoslavia—Dr Yervan Nedelkovich.

Social subject Belgium—Dr Willems, Finland—Dr Severi Savonen, France—Drs P. Braun and Albert Benzonon, Germany—Dr Braennig, Italy—Professor Gioacchino Brocchi, Netherlands—Dr H. R. Gerbrandy, Norway—Dr Nils Ilett, Portugal—Dr João de Almeida, Portugal—Dr Ladislau Patrik, Switzerland—Dr J. Merin.

REPORTS AND NOTICES OF MEETINGS

CONGRESS ON MEDICAL EDUCATION MEDICAL
LICENSURE AND HOSPITALS

The Thirty-Second Annual Congress on Medical Education, Medical Licensure and Hospitals was held at the Palmer House, Chicago on February 17 and 18 1936. It was well attended in spite of weather conditions unfavorable for travel in the northern part of the United States, and interest was maintained throughout the session. While it is

Impossible in the two days to present a comprehensive review of medical education each year an effort is made to focus attention on some limited aspect of especial interest and to note and evaluate certain trends

A shift in emphasis was obvious. Standardization and "Raising of standards" have been slogans in the past, but there is now a much more widespread recognition, than a few years ago that the student is of more importance than the curriculum and the objective is of more importance than the means thereto. It was repeatedly emphasized that the intangibles of education should receive more thought and that the evaluation of education should be qualitative rather than quantitative. These rather inaccurate phrasings were both used freely and criticized freely for in science one cannot escape from the idea of quantity. There is no less need for standards and for quantitative determinations but there is increased awareness of the defects of a mechanical and unintelligent application of quantitative tests. A strong tendency for medical education to become mechanical has been evident.

The resurvey of medical schools made considerable progress in 1935 and will probably be completed by June 1936. Considerable variation has been found in the approved schools, due in part to the increased freedom for experiment in the past ten years and to the stimulation of initiative evident because of the freedom and in part to the development of a certain complacency on the part of schools which were satisfied with having met the generally accepted standards of some years ago. It will be necessary to wait until the completion of the survey for a just résumé of the findings.

The incomplete study suggests however that surveys should be made more often than once in twenty five years, the first having been the Flexner report to the Carnegie Foundation in 1910. It also confirms what had been generally suspected that clinical teaching has not advanced so rapidly nor so far as has teaching in the preclinical and laboratory branches. It was on this account that the so-called "full time" system in the clinical departments was introduced. It is to be hoped that the survey will include some comments on the successes and failures of the various methods which have been introduced in the past twenty five years to improve clinical teaching.

In the survey there has also been an effort to evaluate the schools more by qualitative than by quantitative standards and the character of the student body has received special attention. No public announcement has been made in regard to change in status of any hitherto approved institution but the emphasis on the need for more frequent surveys and the rumors as to unsatisfactory conditions in some of the approved schools indicate that complacency is not now the order of the day. Under stress of curtailment of financial resources in recent years, some institutions have lowered their standards.

Some of the critics of the survey have stated that one of its purposes is to limit the number of medical students and thus ultimately to limit the number of physicians. The survey has no such purpose, regarding these questions as outside of its scope. A possible misunderstanding has arisen however, as the survey has shown that, perhaps for financial reasons, the number of students admitted to certain schools has gravely exceeded the capacity of the material equipment. No limit to the size of the school has been suggested by the survey but it has stated that there is a definite limit to the number of students set by the material equipment, and that increases in the number of students without corresponding increase in equipment impairs the adequacy of the medical education to which the student is entitled. Such inadequacy is intolerable and will not be approved.

The accrediting of educational institutions must continue but better methods for evaluating the end product, the graduate, must be devised. The difficulty in evaluating the intangibles such as character, temperament, and fitness for practice should be regarded as challenges to continued experiment and more intelligent testing.

Who shall do the accrediting? The self-criticism of intelligent and honest teachers may be one of the best methods, but complacency often invades educational institutions. Accrediting by the medical profession, if a practicable scheme be devised ought to be the central core in any comprehensive procedure. Yet this must be supplemented on one side by the contributions of the schools themselves and on the other side by the power of the state exercised through licensing boards. The combination of these three factors probably gives the most just and most penetrating criticism. It is to be remembered that the state cannot give up its police power to be exercised for the protection of the citizens although it may not need to flourish the policeman's stick on every occasion.

Inspection preliminary to accrediting may have an unexpected value. If it is carried on by persons from outside the institution with sympathetic understanding of the problems of medical education in general and those of the institution in particular, it may have a stimulating effect which far more than overbalances the depressing effect of the thought of exercise of the police power.

The problem of the specialist continues to trouble the medical profession and medical schools and boards of registration. Perhaps a peak in the proportion of medical specialists to the whole medical profession was reached in 1930. But some sort of solution is being worked out and within the next year there will be launched additional boards of certification, similar to those for ophthalmology and otolaryngology thus bringing the number of these boards for the specialties up to twelve.

The educational procedure has at least two aspects selective and developing. In the past the selecting

process has been limited to acceptance of students for the school. It is but fair to the candidates to give them opportunities to select by making available to them information about the profession, the requirements, the scope, the opportunities, the limitations, the difficulties, and full and detailed information about medical schools, so that when they choose, it will be with abundant information.

It is well known that occasionally the most fertilizing influences come from the introduction of ideas from another field. It was, therefore, especially interesting to note that more than half of the contributions to the discussions of the first day of the congress were, with the exception of the symposium on obstetrics, by non-medical educators. It may not be quite true that medical education is nine parts education and one part medicine, but a more general recognition by physicians of the ideas and principles of education in other fields might have a powerful leavening effect if given an opportunity to work in the medical school. It is a moot question, things being as they are how education should be carried on at the medical school level. The responsibility of a university in medical education was discussed, the difference between university and professional education was emphasized and it was pointed out that if the university fulfilled its function properly in training the student in the pre-medical course he would be prepared for the medical school. The content of the premedical course is by no means unimportant, but if the student has become educated in the university he may be trusted to learn largely by himself in the medical school. Again the intangibles of medical education are more important than the tangibles.

Standardization and the raising of standards are often accompanied by the idea of restriction of numbers. It is often said, "There are too many physicians." But this scarcely economy is not justified for the capacity of the social organism to absorb and to use well-trained physicians is not known. Such experience as we have indicates that the limit is not fixed. Theoretically there may be an upper limit but for practical purposes it does not yet need to be considered. Here also arbitrary interference with the working of the law of supply and demand is certain to result in deep-seated resentment because of arbitrary discrimination in excluding some persons from privileges which all qualified persons are entitled to enjoy. A clear defect in the education of the physician is that he is not informed as to the social implications of his profession. This is in part due to the medical school, but in no small part to a lack in the pre-medical education which the university or college should contribute through its so-called cultural courses. They should give a background against which reference to the social implications of medicine has some meaning.

One medical specialty was the subject of a symposium. Obstetrics in the undergraduate curriculum. Although there was repeated the charge

that there is a relatively high maternal and infant mortality in the United States, and the statistical basis for the charge was again challenged there was agreement that the rates are inexcusably high. The failure to improve the total rate in spite of the alleged benefits of prenatal care known to have given improvement in some cases, was attributed to increased mortality due to increased interference at delivery. Undergraduate education in obstetrics should be increased so that the proportion of the time of the student given to this subject will more nearly approximate the proportion of the time of the practicing physician devoted to obstetrics. Such increased emphasis will have two important effects. It will give the physician better training for such obstetrics as he may be called upon to practice and it will make him hesitate longer in carrying out so casually interfering procedure at delivery which are actually not entirely free from danger as his inexperience may have led him to believe.

The decision by the Council on Medical Education in the past year to decline to recognize indefinitely the two-year medical schools met with strong protest from these schools so strong in fact that the council changed its decision. These schools present a deficiency which with the swinging of the pendulum toward emphasis on clinical teaching threatens to become serious. Agreement as to just when contact between student and patient should begin is by no means universal and the advocates of the two-year schools claim that the deficiency in their curriculum if any is greatly overbalanced by other considerations. These schools are small, are connected with colleges or universities from which most of their students come and are distant from large centers of population. The students are therefore selected on the basis of far more intimate knowledge than is possible in the large urban medical school with five hundred to a thousand applicants and on the average come from better stock. Their actual records when they finish their course after admission to the four-year schools completely justify their training. As the students often come from homes near the two-year school the financial burden is less heavy for this period of time. There was noticeable among the advocates of the two-year schools a tendency to emphasize the value to any state in their opinion of having a large proportion of its physicians of stock native to that state.

In the discussion of the National Board of Medical Examiners it was brought out that the influence of the Board had extended far beyond the original intent which had been merely to facilitate by its certification the fluidity of movement of physicians throughout the United States from one state to another. This is important and the Board has been successful in this respect, but the part which the Board has come to play directly and indirectly in medical education has been an un-

expected and gratifying byproduct. Although it does not of course claim credit for originating the comprehensive examination its advocacy and use of this procedure have had a widespread influence, and today the work of the Board is far more intimately a part of medical education than ten years ago and its examinations are a far better test of qualifications than twenty years ago when the Board began its work.

At the present time there is a deplorable lack of cooperation on the part of State Boards of Registration in Medicine with the Federal Narcotic Bureau. Perhaps this is just the result of former lack of cooperation on the part of the Federal Bureau but a change in their regulations has made their cooperation possible and a sufficient number of years has elapsed since the change was made to permit cooperation to be widespread. Approximately 80 per cent of the drug addicts and about the same number of violations of the Harrison Narcotic Law in 1933 and 1934 reported to State Boards remain without Board action.

The position of psychiatry in medical education is slowly changing so that it receives more attention but it is not clear that the increased emphasis on the intangible factors in medicine as in the personality of the teacher, the student and the patient is in a major degree due to the efforts of the psychiatrist. Yet he has a great opportunity here and it would seem to be essential that all physicians should have some knowledge of psychiatry for competence in the practice of medicine. State Boards are in a peculiar position. In Massachusetts alone is an examination in psychiatry required by statute and here it is combined with other subjects. In some states psychiatry is introduced under general medicine but in most states it is ignored.

FAULKNER HOSPITAL CLINICAL MEETING

The regular monthly clinical meeting was held at The Faulkner Hospital on Thursday afternoon February 6 at 5:00 P.M.

The first of the two cases for discussion was that of a young girl of seventeen who was well until two months before admission to the hospital and who died two months after. Her symptoms consisted of a lame left foot which she thought was the result of a fall, a hard swelling in the vulvar region on the left and a numbness and soreness in the left hand and left arm. On physical examination there was obviously an anemia, a Horner's syndrome suggesting an injury to the left cervical sympathetic nerves and a hard mass about the size of a small egg in the region of the left iliac which seemed to be attached to the pelvic bones. X-ray studies showed a thinning of the rim of the acetabulum on the left and rarefaction of the pelvic bone in this area. Otherwise the bony framework was normal and the chest was negative. From the x-ray pictures a definite diagnosis was not possible. It suggested several possibilities including atrophy from disease, infectious arthritis and neo-

plasm A biopsy was done on the tumor mass which was found to be not adherent to the bone It was reported by the pathologist as a rhabdomyosarcoma The patient continued to go downhill very rapidly with vomiting and progressive anemia At the autopsy this unusual striated muscle tumor was found to have replaced most of the bone marrow in the body Histological preparations of the various organs were thrown upon the screen so that the actual microscopic lesions were demonstrated About the only place in which blood was being formed was in the spleen which had taken on extra function in this regard

A second case was of special interest because it upsets the generally accepted idea that the end result of acute glomerular nephritis with uremia usually occurs in individuals under forty and is usually preceded with a history of acute nephritis This patient was sixty two years of age and had a family history suggesting vascular disease The past history was negative so far as any disturbance in the kidneys was concerned The patient was well up until four months before admission and died three weeks after admission The picture was typical of uremia with shortness of breath, vomiting, eye-ground changes and hypertension but there was no edema The urine showed albumin, red blood cells, leukocytes and casts and the specific gravity was fixed between 1.013 and 1.017 There was a secondary anemia and a steadily rising nonprotein nitrogen in the blood starting at 108 mgm per 100 cc and eventually reaching 400 mgm The patient showed pronounced sepsis about the teeth At postmortem examination the kidneys were found to be small and pale and the histological sections of the kidneys thrown upon the screen showed the microscopic changes clearly of healed acute glomerular nephritis without the vascular disease that was expected as seen in benign or malignant nephrosclerosis A careful check with the relatives failed to give any indication of when the acute glomerular nephritis occurred The question was raised as to whether absorption from the very bad teeth could cause an acute glomerular nephritis which was overlooked The age of the patient and the absence of any history of acute nephritis make this case quite unusual

Dr Harry C Solomon then discussed the value of fever therapy in various conditions He first reviewed the methods of producing fever as a therapeutic procedure The start in this form of therapy began about 1918 The injection of typhoid vaccines intravenously was one of the earlier methods The fever produced by the typhoid inoculations is unreliable This was followed by the production of malaria in patients Although the fever produced by malaria is satisfactory, there is a certain amount of danger with this procedure A hot bath with temperature around 107° will produce fever up to 105° or 106° in half an hour, but patients are apt to collapse under this form of therapy Diathermy was next introduced with the patient insulated to prevent the radiation of heat from the

body This method is satisfactory with the exception of the danger of burns from poor contacts Radiotherapy was next introduced which is the passage of short wave current through an individual in a radio box which is insulated to prevent the heat from being dissipated Sometimes burns occur from the sparks A large heating electric pad to surround the body is another form. Recently boxes with heated air and high humidity have been devised which are the most satisfactory Dr Solomon pointed out that this form of treatment is not without danger There is a considerable strain upon the individual who is subjected to this rise of temperature There is marked loss of fluid and salt from the body which has to be controlled The blood pressure becomes elevated at the start but soon drops and the diastolic may fall to 0 with threatened vasomotor collapse The pulse rate becomes rapid The blood flow becomes accelerated but often is not sufficient to maintain proper circulation as is noted by mental changes during the treatment The temperature can be elevated to 105°-106° in about one hour and the cooling off process varies with the procedures used but usually takes about two hours These patients usually have the temperature elevated for several hours Occasionally the cerebral control of body temperature disappears and the temperature will not stop rising

Having created a wholesome respect for the dangers and difficulties attendant upon this form of therapy Dr Solomon then took up the conditions in which it has been tried and discussed its value The spirchetes of syphilis are killed in vitro at approximately 103° and fever treatment will kill the spirchetes in the brain tissue in general paresis It is also successful in patients who have a sensitiveness to arsenic and certain gummatous conditions which will not respond to arsenic and mercury He has noted a striking result in interstitial keratitis, syphilitic iritis and uveitis He does not recommend the treatment for the early stages of syphilis The gonococcus is reported to be killed in vitro at a temperature between 105°-106° and favorable results have been reported clinically with fever therapy after a half dozen to a dozen treatments Orchitis and gonococcal arthritis are the conditions most favorably influenced The results in salpingitis have not been so affected although recently good results are reported by a combination of fever therapy and diathermy locally Conditions in which fever therapy has been tried with questionable results are rheumatoid arthritis, streptococcus viridans, endocarditis, peripheral vascular disease, multiple sclerosis and other degenerative diseases of the central nervous system Good results seem to have been accomplished in Sydenham's chorea

HARVARD MEDICAL SOCIETY

The Harvard Medical Society met January 14, 1936, at the Peter Bent Brigham Hospital, Dr John Homans presiding The medical case was presented by Dr L E Putnam A forty five year old male

Italian laborer entered the house nineteen days previously complaining of swelling of the face and neck of six days duration. His past history was negative except for a short period three months previously when he suffered with a stiff neck and "rheumatic" pains in his extremities unaccompanied by either swelling or stiffness. Physical examination on entry showed marked swelling of the face and neck and a dilatation of the veins of the face, neck, and chest. There was a slight peripheral arteriosclerosis. D'Esplene sign was positive and there was dullness over the spines of the upper thoracic vertebrae. The white blood count on admission was 13,000 but immediately subsided to a normal level. X-ray studies revealed increased density of the posterior superior mediastinum. Thrombosis of the superior vena cava, and lymphoma with enlargement of lymph nodes in the superior mediastinum and compression of the superior vena cava were suggested as diagnoses. Therapeutic x-radiation was given, with subsequent slight clearing of the mediastinal shadow, decrease in venous engorgement, and lowering of the venous pressure in the right arm from 300 mm. to 250 mm. of water.

Dr. Sosman commented that the clearing of the mediastinum was not necessarily due to response to the radiation, since development of collateral circulation would produce a similar decrease in the size of the shadow.

Dr. Fulton pointed out that thrombosis of the superior vena cava except from external pressure is extremely rare in occurrence and that pressure from enlarged mediastinal lymph glands alone could easily produce all the signs and symptoms observed in this case.

The surgical case was presented by Dr. Donald B. Hall. A sixty-year-old Jewish male entered the hospital eleven days previously with a history of recurrent attacks of epigastric pain which radiated to the right subscapular region and which were occasionally accompanied by jaundice. Three days before entry he experienced an extremely severe attack. Examination on admission to the hospital showed a marked degree of jaundice, and slight tenderness in the region of the right hypochondrium. The Icteric Index was 60 and the white blood count 16,000. On the seventh day after entry the jaundice had subsided, and cholecystectomy and exploration of the common duct were performed. Culture of the gallbladder after removal was positive for *B. Welchii*. On the first postoperative day his temperature rose to 105 degrees and the white count was 56,000. Examination of the chest was negative except for a few rales at both lung bases. Culture of the wound was positive for *B. Welchii* and the rabbit inoculation test proved the presence of this organism. After forty-eight hours his temperature rapidly subsided and had remained normal for the past two days. There was no crepitus of the wound at any time.

Dr. Catter stated that bilateral pulmonary infarcts probably accounted for fever and that the

B. Welchii in the wound probably played no part in the reaction. The finding of *B. Welchii* in the liver and gallbladder is not uncommon but such organisms seem to be virulent. He believes that they reach the liver by being carried through the portal system, and not by an ascending infection of the biliary tract.

Dr. Francis G. Benedict delivered the paper of the evening on "The Physiology of the Elephant." The physiology and anatomy of the elephant are little known because of the difficulty in procuring animals suitable for study and because of the technical problems presented by the enormous size of these animals. Dr. Benedict's studies were performed on an 8,000-pound female Indian elephant, and sixty-three animals in three circus herds.

Several time-honored myths and fables relative to elephants and their behavior were disproved. The belief that the animals can breathe only through their trunks is false and determinations of metabolic rates by trunk breathing experiments are some forty per cent lower than those determined by means of a respiratory chamber in which the whole animal could be placed. The respiratory exchange of the animal is large amounting to some ten liters of oxygen per minute. Approximately 661 liters of methane gas are given off during the course of twenty-four hours, one-third of which is excreted in the expired air.

Elephants give only very slight indications of their periods of estrus and Dr. Benedict was unable to find the flow of the temporal gland which is supposedly characteristic of the period of sexual activity. The period of gestation varies between eighteen and twenty-two months and the newborn animals stand three feet high at the shoulder and weigh approximately 300 pounds.

Elephants do not reach the great ages recounted in fiction and an eighty-year-old animal is to be considered quite old. The average age of the circus animals is about thirty years. The average animal weighs approximately 6,000 pounds and its shoulder height is about seven feet, four inches. Exceptionally large animals may weigh 8,000 pounds and stand eight feet at the shoulder.

The respiratory rate while standing varies between five and ten per minute and is only four or five per minute when the animal is lying quietly. The heart rate could not be determined directly but was obtained by means of electric leads and a galvanometer in a manner similar to that used in electrocardiography. It was discovered that the heart rate of the animal while lying was about seven beats per minute higher than when it was standing, the rates being thirty-five and twenty-eight beats per minute respectively.

The body temperature of the elephant was ascertained indirectly by determining the temperature of recently excreted urine and feces and was found to be approximately 35.9 degrees centigrade. (96.6 degrees Fahrenheit.)

The food intake amounts to about 150 pounds of

hay each day, and some fifty gallons of water are consumed during a twenty-four hour period

Studies of urinary constituents, and of intake and output, have shown a low endogenous metabolism. The approximate basal metabolic rates of the 8,000-pound animal studied by Dr Benedict was 49,000 calories per twenty-four hours, or thirteen calories per kilogram, and 2,060 calories per square meter of body surface. One large animal produces as much heat as thirty men.

The elephant's legendary fear of mice does not exist, and they are not in the least perturbed by either rats or mice running over their bodies.

NEW ENGLAND PHYSICAL THERAPY SOCIETY

The regular meeting of the New England Physical Therapy Society will be held at the Hotel Kenmore, Boston, on Wednesday evening, March 18, 1936, at 8 P M

PROGRAM

Static Foot Conditions and Their Treatment—

Howard Moore, M D, Boston

The Discussion will be opened by George E Deering, M D, Worcester

The Council will meet at six

Dinner will be served to members and their guests in the main dining room at six thirty

Physicians and medical students are cordially invited to attend

WILLIAM D McFEE, M D, *Secretary*

41 Bay State Road, Boston

NEW ENGLAND OPHTHALMOLOGICAL SOCIETY

The 309th meeting of the New-England Ophthalmological Society will be held on Tuesday, March 17, 1936, at the Massachusetts Eye and Ear Infirmary, 243 Charles Street, Boston

9 00 A M Clinic and Operating Room

11 30 A M Neuro-Ophthalmological Conference

8 00 P M

CASES

Corneal Dystrophy—Dr Trygve Gundersen

Sarcoma of Iris—Dr William P Beetham

Choroideremia—Dr J Herbert Waite

PAPER

Experimental Exophthalmos—Dr Harry B Friedgood

DR. WILLIAM P BEETHAM,

Secretary-Treasurer

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, March 24, at 8 15 P M

PROGRAM

Presentation of Cases

The Genesis of Thyroid Proteins By Dr William T Salter

Magnesium Metabolism in Health and Disease By Dr Joseph C Aub

Medical students and physicians are cordially invited to attend

MARSHALL N FULTON, M D, *Secretary*

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

A meeting will be held at St Elizabeth's Hospital, Brighton, on Wednesday, March 18, at 8 P M

PROGRAM

1 Report of a Case of Abdominal Pregnancy Demonstration of specimen—George F Keenan, M D

2 Report of a Case of Bilateral Pyelonephrosis with Giant Calculi Demonstration of x rays.—Edward J O'Brien, M D

3 Bronchoscopy as an Aid in Diagnosis, with X Rays—John E Burns, M D

4 Industrial Dermatitis, with Lantern Slides—John G Downing, M D

5 Use of Living Sutures in Repair of Recurrent Inguinal Hernia. Lantern Slides—Edward M Hodgkins, M D

6 Peripheral Vascular Disease, and Demonstration of Pavaex Machine—John F Casey, M D

7 Demonstration of Pathological Specimens—Francis P McCarthy, M D

The meeting will begin promptly at 8 P M and it is expected that no paper will take more than fifteen minutes

Members of the Society are urged to bring guests. Internes and medical students as well as any physician not resident in this District are cordially invited

A buffet supper will be served after the meeting

SUMNER H REMICK, M D, *President*,

ALEXANDER A LEVI, M D, *Secretary*

THE BOSTON MEDICAL HISTORY CLUB AND THE BOSTON MEDICAL LIBRARY

The Boston Medical History Club and The Boston Medical Library will hold a joint meeting on Monday, March 16, at 8 15 P M in John Ware Hall, 8 Fenway, Boston

"The History of the Lymphatics"—By Professor John F Fulton, M D, Sterling Professor of Physiology, Yale University

BENJAMIN SPECTOR, M D,

Secretary, Boston Medical History Club

In connection with the address, there will be an exhibition of books from the collection of the Boston Medical Library

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Boston Lying in Hospital, Monday, March 23, at 8 15 P M. The program will be announced later. All members of the New England Heart Association and interested physicians are invited to attend

JAMES M FAULKNER, M D, *Secretary*

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY MARCH 16 1936

Monday March 16—

- 8 16 P.M. Joint Meeting of the Boston Medical Library Club and the Boston Medical Library 8 Fenway Boston

Tuesday March 17—

- 9 10 A.M. Boston Dispensary 55 Bennet Street Boston. Analysis of Case of Poliomyelitis seen on the District Service During the 1935 Epidemic Dr. Edith Robinson.
- 9 A.M. 11 30 A.M. 8 P.M. New England Ophthalmological Society Massachusetts Eye and Ear Infirmary 13 Charles Street, Boston
- 12 M. South End Medical Club at the office of the Boston Tuberculosis Association 554 Columbus Avenue Boston.
- 20 P.M. Pediatric Ward Visit Massachusetts Eye and Ear Infirmary

Wednesday March 18—

- 9 10 A.M. Boston Dispensary 55 Bennet Street Boston. Quantitative Studies in Nasal Pollution. Dr. H. J. Sternstein
- 11 M. Clinico Pathological Conference Children's Hospital
- 8 P.M. New England Physical Therapy Society Kenmore Boston
- 8 30 P.M. Greater Boston Bikur Cholim Hospital 48 Townsend Street, Roxbury

Thursday March 19—

- 8 30-9 30 A.M. Clinic Surgical Staff of the Peter Bent Brigham Hospital at the Peter Bent Brigham Hospital
- 9 10 A.M. Boston Dispensary 55 Bennet Street Boston. Social Service Case Presentation. Miss Edith R. Canterbury
- 8 30 P.M. Medical Clinic at the Peter Bent Brigham Hospital

Friday March 20—

- 9 10 A.M. Boston Dispensary 55 Bennet Street Boston. Studies in the Interrelation of the Thyroid and Adrenal Glands Dr. Elliott C. Cutler

Saturday March 21—

- 9 10 A.M. Boston Dispensary 55 Bennet Street Boston. Hospital Case Presentation. Dr. S. J. Thannhauser
- 10 11 Staff rounds at the Peter Bent Brigham Hospital

Sunday March 22—

- 1 P.M. Free Public Lecture, Harvard Medical School Building D Longwood Avenue. Chronic Diseases at the Crossroads. Dr. H. L. Lombard

Open to the medical profession
Open to Fellows of the Massachusetts Medical Society

March 13—William Harvey Society will meet at 8 P.M. in the Auditorium of the Beth Israel Hospital, Boston.

March 16—Joint meeting of the Boston Medical History Club and the Boston Medical Library See page 560

March 17—New England Ophthalmological Society See page 560

March 17—South End Medical Club will meet at the office of the Boston Tuberculosis Association 554 Columbus Avenue Boston

March 17—Lawrence Cancer Clinic at the Lawrence General Hospital 1 Garden Street at 10 A.M.

March 18—New England Physical Therapy Society See page 560

March 18—Greater Boston Bikur Cholim Hospital will hold a medical meeting at 8 30 P.M. 48 Townsend Street, Roxbury

March 19—Medical Clinic, Peter Bent Brigham Hospital See page 561

March 23—New England Heart Association See page 560

March 24—Harvard Medical Society See page 560

March 30—Springfield Medical Association 8 30 P.M. at the rooms of the Springfield Academy of Medicine, 70 Maple Street. The Development of Surgical Practice in Springfield. Dr. John M. Birnie.

April 8—Joint Meeting of the Massachusetts Tuberculosis League and the Hampden County Tuberculosis and Health Association. See "An address by Dr. Kendall Emerson." Page 493 issue of March 5

April 20-24—A. Postgraduate Institute in Philadelphia. See page 491. Issue of March 5

May 12-16—The International Congress of Physical Medicine See page 445 issue of February 7

June 15-19—The Executive Board of the Catholic Hospital Association will meet at the Fifth Regiment Armory Baltimore Md.

June 16-July 28—Summer Course in Bacteriology See page 255 issue of February 7

September 1936—First International Conference on Fever Therapy See page 125 issue of December 6 1935.

September 7-10—International Union against Tuberculosis See page 554

SUFFOLK DISTRICT MEDICAL SOCIETY

March 18—Meeting at the Boston Medical Library The Laboratory and Clinical Story of Fatigue Dr. Arlie V. Bock and Dr. David B. Dill. Discussion Dr. Donald J. MacPherson and Dr. Augustus Thorndike Jr.

April 29—Annual Meeting at the Boston Medical Library The Treatment of Septicæmia. Dr. Champ Lyons. The Pleurothly of Scarlatinal Streptococcus Toxin Dr. Sanford B. Hooker. Discussion: Dr. Hans Zinsser

The medical profession is cordially invited to attend these meetings.

ROBERT L. DENORMANDIE, M.D. President.

CHARLES C. LUND M.D., Secretary

WORCESTER DISTRICT MEDICAL SOCIETY

April 8—Wednesday evening. Hahnemann Hospital, Worcester Mass. Dinner and scientific program. Subjects of program to be announced later

May 13—Wednesday afternoon and evening. Annual Meeting of Society. Time, place and details of program to be announced in an April issue of the Journal.

ERWIN C. MILLER, M.D. Secretary

27 Elm Street, Worcester

BOOK REVIEWS

Public Health Administration in the United States
Wilson G Smillie 458 pp New York The Macmillan Company \$3.50

This book is a summary of the ways and devices employed by the various public health administrators of today, and it suggests their trends and goals for tomorrow. As one reads it he feels that public health administration must be an individual application of more or less arbitrarily conferred powers.

The section on the control of communicable disease contains 120 pages. It is a little too conventional to be instructive from the clinician's point of view, for example, the active immunization of dogs against rabies by a single injection "has been applied successfully", and typhoid vaccination "has proved very popular". One would rather have a statement of evidence for the value of such widely practiced procedures. Amebiasis and trichinosis are not discussed, although meningococcus meningitis and poliomyelitis are each given five pages.

About 130 pages are devoted to chapters on the basic activities of health administrators. Many of these are very well done—particularly the chapter on public health nursing—and it is in this section that the most informative reading will be found.

The remaining pages describe the formulation of basic activities into public health programs by rural, municipal, state and federal government departments. For the casual reader the continued discussion of these basic activities becomes somewhat repetitious toward the end of the book. Repetition, however, is good pedagogy—and this is essentially a textbook for students of Public Health Administration. There are other chapters on disaster relief, budgets, etc., to round out the whole subject of community health organization. Of these the chapter on voluntary health organizations is perhaps most worthy of a wider circulation than it will attain in this book.

The book itself should be read by every public health administrator and by many others. Indeed, it would be well if it were read by each member of the great army that flavors its social vanity with charity.

Thermal Processes for Canned Marine Products
Volume 2 O W Lang 182 pp California University of California Press

This publication gives the results of a bacteriological inquiry into the canning of marine products on the Pacific Coast. The investigation was inspired by the occurrence of two fatal cases of botulism following the ingestion of sardines canned in tomato sauce and originating in California.

The monograph sets forth the results of the subsequent investigation of canning procedures in the case of the following marine products: Abalone, kamaboko (Japanese style preparation from barracuda), mackerel in brine, sardines, shad, shad roe, squid, tempura (Japanese style barracuda fish cakes), tuna, mackerel in oil, bonito and yellow tail. The general phases are covered by the investigation of

(1) the bacterial flora of canning plants, (2) the heat resistance of botulinus spores, (3) the heat penetration rates in canned marine products in various types of pack, and cans of different dimensions and styles, and finally a study of processing times required to secure certain sterilization in canned products previously infected with spores having a greater heat resistance than botulinus spores.

The results obtained in this comprehensive investigation which was both well conceived and well carried out result in recommendations of great practical utility to the canning industry.

National Medical Monographs Commoner Diseases of the Skin. S William Becker 283 pp New York National Medical Book Company, Inc

This little volume should be of special interest to the general practitioner. The common skin diseases are considered from a somewhat different viewpoint in many instances as compared with the average textbook. There is no introduction containing anatomy, physiology, etc., and one is plunged immediately into the discussion of diagnosis and treatment. Much stress is placed on the functional dermatoses, especially the "neurodermatoses" and the need for considering the background of the individual patient as well as the manifestations on the skin. A limited formulary is given but the directions for its use are detailed. The photographs are excellent.

Modern Home Medical Adviser Your Health and How to Preserve It Edited by Morris Fishbein 905 pp New York Doubleday, Doran & Company, Inc

The reviewer had supposed that Modern Home Medical Advisers disappeared with the high wheel bicycle. But human nature being what it is, here is an old friend, brought up to date with photographs of blood transfusions, children's clinics, rescue of the drowning and discussions of allergy and contraception.

There are twenty-three collaborators, seven of whom hail from Chicago, three each from Rochester and New York and one each from Kansas City, Ann Arbor, Iowa City, Winston Salem, Boston, Cleveland, Cincinnati, Philadelphia, Indianapolis and Toronto.

Were a medical reviewer inclined to be critical he could find much to comment upon in these nine hundred pages. It is the sort of material which appears monthly in *Hygeia* and those who enjoy reading the one will enjoy reading the other. Not trusting himself for a true appraisal, the reviewer lent the volume to two of his lady patients. Their reactions may be summed up by stating that one considered the work "splendid", the other considered it "valuable". It is probably indispensable to the sort of person who must be up to date in his medical lingo. It is beautifully printed and bound and will thus be appreciated on the library shelves of the Intelligentsia.

The New England Journal of Medicine

VOLUME 214

MARCH 19, 1936

NUMBER 12

GASTROSCOPIC OBSERVATIONS IN NEOPLASM*

BY EDWARD H. BENEDICT, M.D.†

GASTROSCOPY has been practiced for many years with rigid instruments but since the invention in 1932 of the Wolf Schindler¹ flexible gastroscope its practice has increased rapidly. The flexible gastroscope was first used in this country in 1933 at the Massachusetts General Hospital², and is now used in a number of the larger clinics in the United States.

With regard to gastroscopy in ulcer and cancer Schindler⁴ concludes in a recent article "Gastroscopy not only supplements the roentgen examination in the direct diagnosis of gastric ulcer and gastric neoplasm, but it aids greatly in their differential diagnosis. It also furnishes direct evidence of the progress of the benign lesions and of the degree of involvement in cases of neoplasm."

A brief review of the x ray and gastroscopic findings in the following cases shows the importance of gastroscopy as an aid to the x ray in the diagnosis and localization of neoplasm.

1 M M M G H. No 333930 male aged fifty three

X Ray 5/22/34 There was a large crater in the region of the incisura of the stomach with very marked infiltrative changes around the crater. Re-examination was requested.

Gastroscopy 5/24/34 There were numerous areas of bright red submucous hemorrhage. On the lesser curvature one small rounded dark area $\frac{1}{2}$ cm. in diameter and a larger similar area about $1\frac{1}{2}$ cm. in diameter were seen and were thought to represent benign ulceration. There was no evidence of carcinoma.

X Ray 5/26/34 There was a large crater with extreme infiltration around it extending nearly to the greater curvature. The degree and type of infiltration were much more suspicious of malignant degeneration than of simple inflammatory changes around a benign ulcer.

Operation, 6/3/34 A definite ulcer of the posterior wall and lesser curvature of the stomach was felt to superimpose upon the pancreas. The ulcer margins were hard, irregular and the crater admitted the tip of the finger. The hardness resembled malignant disease. It was thought wise to resect the stomach as it was felt that the lesion might be malignant.

Pathological Report Gastric ulcer. No evidence of malignancy.

Comment Pathological report confirmed the gastroscopic diagnosis of a benign lesion. By gastroscopy a ragged nodular lesion with a dirty

base usually means carcinoma. In this case the lesion appeared clean with smooth margins and was therefore thought to be benign.

3. M M M G H. No 318232 female aged forty nine.

X Ray 10/13/34 There was a large ulcerating lesion involving the greater curvature of the upper third of the stomach. The ulcer niche was 2 cm. in depth but the greater bulk of the lesion was above the ulceration. Findings were those of carcinoma involving the greater curvature.

Gastroscopy 10/16/34 There was some irregularity of the greater curvature in the upper part of the body of the stomach. The folds in the cardiac portion ran somewhat irregularly and were large and tortuous, sometimes ending abruptly. No niche or definite tumor was seen. The findings are consistent with a marked hypertrophic gastritis. Early carcinoma is a possibility.

Operation, 10/17/34 The most careful examination of the stomach failed to reveal the slightest evidence of carcinoma. In view of a very suggestive history of gallbladder disease and a thick, obviously inflamed gallbladder a cholecystectomy was done.

Comment It was impossible here to reconcile the x ray and gastroscopic findings. Certainly by gastroscopy no large carcinoma was seen and it seemed unlikely that a large neoplasm had been overlooked. Marked hypertrophic gastritis may however simulate an early infiltrating carcinoma.

3. E. V. T. M G H. No 311863 female aged thirty-seven.

X Ray 11/8/34 There was an obstructing lesion at the pylorus with sixty per cent retention of barium. Re-examination after gastric lavage was requested.

Gastroscopy 12/13/34 The pylorus was well seen. On the anterior margin of the pylorus toward the lesser curvature there was a small nodular nipple-like excrescence about 5 mm. in diameter and bright red in color. Peristalsis was very inactive but the pylorus was seen to contract close to this nodule. The lesser curvature appeared irregular, indurated and gave a somewhat hard appearance, as though infiltrated. There was no peristalsis passing over it. There was one slightly depressed area in this region, suggesting an ulceration. The greater curvature and posterior wall were intensely red and glistening with irregular tortuous rugae. The gastroscopic findings are consistent with an infiltrating type of carcinoma and a marked gastritis.

X Ray 12/14/34 A lesion 3 cm. in diameter with in $1\frac{1}{2}$ inches of the pylorus appeared to be a small polypoid growth without a stalk.

Operation 12/17/34 One inch from the pylorus on the anterior wall of the stomach could be felt a very small indurated area in the mucosa. A Billroth II resection was performed.

From the Massachusetts General Hospital.

Pathological Report Adenocarcinoma Acute and chronic gastritis

4 A J W M G H No 343261, male, aged sixty three

X-Ray, 2/11/35 The stomach showed a smooth constriction involving its middle two-thirds. Only a thin stream of barium passed through this region. The rugae were completely obliterated, and at one place on the lesser curvature there was a small polypoid filling defect. The findings were those of an annular malignancy involving the middle third of the stomach.

Gastroscopy, 2/13/35 A fair view was obtained of the upper part of the stomach, but the lower half could not be seen, probably because of the annular constriction described by x-ray. The mucosa was nowhere normal, but in its place was an intensely red, fungating, slightly elevated mass, which in some places appeared ulcerating and in other places nodular. The lesion appeared to extend practically to the esophageal orifice and its operability from the gastroscopic appearance would therefore seem quite doubtful.

Operation, 2/19/35 Exploration revealed extensive carcinoma of the stomach, which extended from the cardia to within two and a half inches of the pyloric ring. Involved glands were felt along both the lesser and greater curvatures of the stomach. Even total gastrectomy was found to be impractical on account of the extension of the growth into the transverse mesocolon, a little to the right of the ligament of Treitz. The stomach was so extensively involved that gastroenterostomy could not be done above the growth.

Comment Gastroscopy here established the extent of the lesion and its probable inoperability.

5 J F F M G H No 340894, male, aged fifty-seven

X-Ray, 10/19/34 The lesser curvature of the stomach appeared rather rigid, but could not be palpated. No peristaltic waves passed over the lesser curvature. The distal third of the stomach was narrowed, and no normal rugae could be seen in this region. One or two small filling defects were noted. The findings were consistent with a carcinoma of the scirrhus type, of the pyloric third of the stomach.

Gastroscopy, 10/25/34 No normal mucosa was seen anywhere in the stomach. The antrum was occupied by an annular lesion that appeared infiltrating, but also slightly nodular and protruding. The color was bright red. No normal rugae were seen. In the upper part of the stomach the irregularities were less pronounced and may represent a marked verrucous gastritis, or may mean that the lesion is infiltrating fairly high.

Operation, 10/26/34 The stomach was involved in a very extensive carcinoma which was entirely inoperable. It had grown upward toward the esophagus and backward into the retroperitoneal tissue with numerous and large glands.

Comment Here again gastroscopy suggested a very high lesion. Gastroscopy may be particularly helpful when the stomach is inaccessible to palpation, and therefore more difficult for roentgen diagnosis.

6 M F B M No 16292, male, aged fifty-five

X-Ray, 11/23/34 The stomach was unusually high in position, very small, and emptied rapidly. There appeared to be an annular constriction involving

about half of the stomach, having the general appearance of scirrhus carcinoma. Palpation was impossible, due to inaccessibility of the stomach. In spite of a negative Hinton reaction, it was felt that syphilis could produce this picture.

Gastroscopy, 11/24/34 Toward the lesser curvature there was a crater about 2 cm in diameter, the margins of which appeared ulcerating and the edges irregular. No normal mucosa was seen anywhere in the stomach. The entire mucosa appeared studded with nodular protuberances, which seemed to extend almost to the cardia. The appearance was that of a constricting ulceration of the body of the stomach, with infiltration of most of the upper part. The lesion was felt to be malignant.

Operation, 11/30/34 Exploration showed four fifths of the stomach involved in new growth, which was adherent posteriorly, and extended up to the esophageal opening. The growth was entirely inoperable. A lymph gland along the mesentery was removed for biopsy.

Pathological Report Metastatic adenocarcinoma

Comment Gastroscopy was requested here by the X-Ray Department in order to help exclude the possibility of syphilis.

7 M K M G H No 337960, male, aged forty-five

X-Ray, 3/21/34 There was a large amount of fluid in the stomach. The rugae were somewhat enlarged. The findings were those of hypertrophic gastritis.

Gastroscopy, 4/5/34 The mucous membrane exhibited a warty appearance which was so marked in some places as to suggest malignant disease.

X-Ray, 6/21/34 Gross distortion of all the gastric rugae was still present. The lesser curvature at the junction of the cardia with the body of the stomach was stiff throughout the examination. A definite lesion was not demonstrable. Re-examination was requested.

7/7/34 There was an ulceration along the lesser curvature of the stomach extending almost to the antrum. Within this ulceration there was a projection about 1 cm wide and ½ cm deep. The rugae in the body of the stomach were definitely enlarged. Considerable fluid was present. The findings were thought to be those of ulcer in the middle portion of the lesser curvature with probably a second ulcer just below it and very extensive infiltration. On account of this extreme infiltration, malignant changes were considered possible.

Operation, 7/11/34 An inoperable neoplasm of the stomach was found.

Comment Although this case has been previously reported³, the suspicion of carcinoma by gastroscopy three months before it was suspected by x-ray is worth emphasizing.

8 C A M G H No 337178, male, aged forty-nine

X-Ray, 5/18/34 There was a large lobulated mass about the size of a fist in the posterior medial part of the fundus of the stomach, consistent with a cauliflower-like carcinoma. The lower portion of the stomach was normal and there was no obstruction of the cardia.

Gastroscopy, 5/22/34 The pylorus was well seen and around it the mucosa was somewhat pale and a little irregular. In the upper half of the stomach, on the greater curvature and posterior wall, an excellent view was obtained of a cauliflower-like lesion of a whitish gray color, with bright red streaks of blood running across it. This appeared to connect with an irregular ulcerating lesion involving the

posterior wall and extending up practically to the cardia. From the gastroscopic appearance it looks as though cure could only be effected by total gastrectomy if at all.

Operation, 5/31/34 Exploration disclosed a freely movable mass in the fundus of the stomach close to the esophageal opening and involving the posterior wall and greater curvature. The upper two-thirds of the stomach was removed and an anastomosis made between the antrum of the stomach and the esophagus.

Pathological Report Adenocarcinoma.

Comment In this case gastroscopy was of assistance in determining the extent of the lesion and indicating that removal of the stomach up to the esophageal opening would probably be necessary.

9 S N F M G H No 263438 male aged fifty-eight.

X Ray 11/14/34 The patient was unable to swallow more than two mouthfuls of barium without vomiting. A large carcinoma involving the lower four-fifths of the stomach was demonstrated.

Gastroscopy 11/18/34 In place of the normal mucosa there appeared a nodular proliferative and in some places ulcerating neoplasm which was a bright red to gray color in various locations. The lesion appeared to be very extensive and was thought to be inoperable.

Operation 11/17/34 There was a huge carcinoma of the stomach extending backwards into the tissues behind so that removal was entirely impossible. A lymph node was removed for biopsy.

Pathological Report Metastatic carcinoma.

Comment A gastroscopy in this case correctly suggested an inoperable lesion. Although it is, of course, frequently impossible to be sure by any diagnostic procedure that a given lesion is inoperable, all methods at our disposal should be employed, and gastroscopy in doubtful cases may be of very great value.

10 F D F M G H No. 333523 male aged fifty-seven.

X Ray 8/31/33 Examination showed a lesion which had the appearance of carcinoma of the greater curvature of the stomach about one inch from the pylorus.

11/22/33 Reexamination confirmed the previous findings. There was fixation of the lower three inches of the stomach, with deformity of the greater curvature and definite evidence of obstruction.

Gastroscopy 11/25/33 An extensive lesion was seen which appeared to involve most of the greater curvature and parts of the anterior and posterior walls. The appearance was that of extensive ulcerating carcinoma.

Operation, 11/28/33 There was an extensive carcinomatous, primary in the stomach with metastases scattered throughout the peritoneal cavity one of which was removed for diagnosis.

Pathological Report Metastatic carcinoma.

Comment Here again gastroscopy suggested a very extensive lesion.

11. C. R. M M G H No 340431 female, aged fifty-four.

X Ray 10/6/34 Examination showed a carcinoma involving the middle half of the stomach with question of extension up to the cardiac orifice.

Gastroscopy 10/3/34 The lower part of the stom-

ach could not be seen as the gastroscope was obstructed probably by the tumor. The tumor appeared both ulcerative and proliferative and involved the greater curvature posterior wall and lesser curvature extending it was thought to within one inch of the cardia. No normal rugae were seen. The examiner felt that the chances of resection were small.

Operation 10/10/34 There was a very large carcinoma of the stomach extending up almost to the cardia and backwards around the great vessels. Radical removal was entirely out of the question. A small specimen was obtained for biopsy.

Pathological Report Metastatic adenocarcinoma.

12. A. S. M G H No 342303 male aged fifty-seven.

X Ray 12/27/34 Stomach was high and transverse and practically impossible to palpate. The lower half of the lesser curvature was constantly deformed by a dish-like ulceration. Peristalsis was practically absent. X-ray findings were consistent with a large malignant ulceration involving the lower half of the stomach and located mostly on the lesser curvature.

Gastroscopy 12/31/34 About two inches inside the cardia there was a definite nodule projecting from the lesser curvature. This nodule was somewhat reddened near the base and whitish at the apex. Near this region the mucosa seemed somewhat pale. There was no peristalsis. Below this nodule the gastroscope met with obstruction. The findings were felt to mean an infiltrating type of carcinoma extending fairly high along the lesser curvature.

Operation 1/4/35 A very high subtotal resection of the stomach was performed for carcinoma of the lesser curvature.

Pathological Report Adenocarcinoma.

13 E. S. M G H No 338278 male aged sixty-five. Pernicious anemia and gastric tumor.

X Ray 6/26/34 There was an irregular filling defect showing evidence of craters involving the lower half of the stomach. The duodenum showed a constant deformity which appeared to be extrinsic. The findings were those of carcinoma involving the lower half of the stomach with extrinsic compression defect of the duodenum.

7/6/35 Reexamination confirmed the previous observation. There was a large defect in the pyloric end of the stomach.

Gastroscopy 7/6/34 The entire mucosa was very pale and thin so that numerous small blood vessels could be seen very well. Normal rugae were almost entirely absent. On the lesser curvature and posterior wall in the antrum of the stomach there was a rounded elevated red lesion which was fairly smooth in contour and which was attached to the mucous membrane by a broad base. The lesion appeared to be about 7 or 8 cm in length and was thought to be a large benign polyp although malignant degeneration at the base was considered a possibility. The general appearance of the mucosa was typical of the atrophy seen in pernicious anemia.

Operation 8/7/34 The stomach was delivered without difficulty. In it could be felt a definite polyp. The stomach was opened and arising from the posterior wall about one-third of the way up from the pylorus was a long tongue-like polyp about 15 cm. in length and ulcerated in two places. It was excised with a wide margin around the base.

Pathological Report Gastric polyp. No evidence of malignancy.

Comment Clinically this patient had a typical pernicious anemia. The mucosa in untreated pernicious anemia is characteristically very

smooth and pale, and so thin that blood vessels can be plainly seen shining through. After liver therapy improvement in the appearance of the mucosa has been noted.⁵ The appearance of the tumor as seen through the gastroscope is shown in the accompanying illustration (fig 1). From

FIGURE 1 Gastroscopic appearance of benign polyp (Case 13)

that appearance alone a benign lesion seemed almost certain, but with a slightly ulcerated and nodular appearance at the base malignancy could not be excluded. As the polyp was turned on itself, its length appeared foreshortened as seen through the gastroscope. Since operation and liver therapy this patient has improved remarkably, and is now in very good health. The mucosa has also improved very definitely both in color and general appearance, so that by gastroscopy there is no longer a definite atrophy, but rather a superficial gastritis.

14 D J M M G H No 332957, male aged fifty-one. ? Gastric pathology or extrinsic mass.

X-Ray, 11/1/33 There was marked deformity of the antrum, pylorus, and duodenal loop. The antrum and pylorus appeared to be displaced upward and fixed. The rugae were seen throughout the lower end of the stomach, and faint peristaltic waves passed over the narrowed and displaced antrum of the stomach. Definite x-ray evidence of disease of the stomach could not be demonstrated on two examinations. The deformity was probably from extrinsic involvement.

Gastroscopy, 11/3/33 The mucosa and rugae of the antrum and body of the stomach appeared normal throughout. The pylorus also appeared normal.

COMPULSORY STERILIZATION

In Germany, the law of July 14, 1933, makes compulsory the sterilization of all individuals with serious diseases (congenital mental debility, depressive manic psychosis, epilepsy, Huntington's chorea, hereditary deafness, hereditary blindness, serious malformations and alcoholism) which, according to medical knowledge, have a great possibility of resulting in deficient offspring. This law does not apply to drug addicts, nor to apparently normal individuals with one or more children with manifestly hereditary diseases. All the cases are submitted for judgment to a sanitary council composed of a judge, a government physician and a practicing physician. The patient may appeal against the decision to a

Operation, 11/23/33 There was a large mass in the body of the pancreas which seemed to infiltrate the posterior wall of the stomach. The liver contained many metastatic nodules. There were hard, firm glands along the common bile duct, and nodules in the peritoneum and in the pelvis. A gland was removed from the peritoneum for biopsy.

Pathological Report Metastatic adenocarcinoma.

Comment Gastroscopy has in several cases, as in this one, been useful in helping to exclude intrinsic disease of the stomach.

Diagnostic gastroscopy is used as a very helpful supplement to x-ray examination in diseases of the stomach. It is not offered as a substitute for the Roentgen ray, since it is admitted that the latter is indispensable in the diagnosis of gastric pathology. In fact, since esophageal disease may be a contraindication to gastroscopy, x-ray study of the esophagus and cardiac orifice should always be carried out as a preliminary procedure. Patients with stomach complaints, even if vague and of short duration, should have early x-ray examination, followed in selected cases by gastroscopy.

A study of the cases presented above reveals that gastroscopy in neoplasm of the stomach may be a very valuable adjunct to the x-ray.

- 1 In making an early diagnosis of carcinoma,
- 2 In differentiating benign and malignant lesions,
- 3 In determining the location and extent of the lesion, and
- 4 In excluding intragastric pathology.

special court which has final jurisdiction. Wegner (1934) believes that 30 per cent of the cases of blindness may be prevented thanks to this law. There are, however, in the author's opinion, certain disadvantages to compulsory sterilization. The main one to be feared is that the patient, apprehensive of being declared to the competent authority, will see the physician as infrequently as possible, and will furnish him with an inexact history, thereby rendering the physician's task more difficult and preventing him from properly treating certain patients. —Excerpts from the address of Professor Franceschetti before The General Assembly of the International Association for Prevention of Blindness, London, April 5, 1935.

NEW ENGLAND SURGICAL SOCIETY

SALMONELLA SUPESTIFER INFECTION
WITH SURGICAL COMPLICATIONS*

BY IRVING J. WALKER, M.D.,† SOMA WEISS, M.D.,† AND ROBERT N. YE, M.D.†

IT is the purpose of this communication to report two instances of *B. supestifer* infection with unusual clinical course and localized lesions, and to collect from the literature such others as have been reported to date.

The causative organism of this rather rare infections disease of human beings, the *B. supestifer*, is accepted as belonging to the *Salmonella* group, perhaps better known as the paratyphoid group of organisms. It is now agreed that the above mentioned disease of the porcine species, formerly believed to be the cause of hog cholera in this country, and Schweinepest in Europe, is due to a filtrable virus and that the *B. supestifer* is a secondary invader or saprophyte.

BACTERIOLOGY

Until quite recently it has been customary in most American bacteriological laboratories to employ a relatively simple classification for the pathogenic Gram negative bacilli. Those fermenting lactose were considered members of the colon bacillus group, whereas those not fermenting lactose were placed in the typhoid paratyphoid-dysentery group. Further subdivision of the latter was made on the basis of motility, sugar fermentations and specific agglutination tests. Dysentery bacilli are non motile and do not form gas with fermentable sugars. Typhoid bacilli also fail to form gas but are actively motile. All strains forming gas with fermentable sugars were placed in the paratyphoid group. If xylose, a rare sugar, was fermented and if agglutination was obtained with anti *B. Paratyphosus A* serum the strain was reported as *B. Paratyphosus A*, otherwise it was reported as *B. Paratyphosus M*. It was realized that many different species gave the same reactions as the latter, but so little was known that further separation was impossible.

Within the past few years many contributions have been made, particularly by White and by Andrewes in England, which have served to clarify our knowledge of this paratyphoid group. More than twenty different species can be identified by specific agglutination tests, other species have been described and probably many more will be reported.

From the Second Medical Service, Fifth Surgical Service and Department of Pathology, Boston City Hospital.
Read at the Annual Meeting of the New England Surgical Society at Manchester, New Hampshire, September 27, 1935.

*Walker, Irving J.—Clinical Professor of Surgery, Harvard University Medical School. Weiss, Soma—Associate Professor of Medicine, Harvard University Medical School. Ye, Robert N.—Instructor in Bacteriology and Immunology, Harvard University Medical School. For record and add cases of authors see "This Week's Issue," page 534.

This paper is concerned only with the snipes tifer Hirschfeld subgroup of which there are three very closely related strains: (a) the American type (hog cholera bacillus diphasic type of White, Group I of Andrewes), (b) the Eastern type (*B. Paratyphosus C* of Hirschfeld), and (c) the European type (monophasic type of White, Group II of Andrewes). Although positive identification should be made only on the basis of specific agglutination tests, a presumptive diagnosis can be made from certain biological reactions. All ferment dextrose, xylose and mannite with the formation of acid and gas, but fail to ferment saccharose and lactose. The American and European types fail to ferment arabinose and can be differentiated one from the other by the fact that the European type forms H_2S in lead acetate agar. The Eastern type ferments arabinose with the formation of acid and gas, but fails to ferment inositol. It can be differentiated from several other species with identical biological reactions only by means of specific agglutination tests.

Instances of isolated and endemic gastrointestinal infection of the human being due to the *B. supestifer* occur relatively commonly in Europe and to a lesser extent in the United States, especially since the World War.

While undoubtedly the *B. supestifer* infection of the human being is the result of food contamination, the sources of these infections have remained undetermined and no definite relationship between the human and infected pigs or pork has been established.

Instances of septicemia associated with the *B. supestifer* are not uncommon and probably account for the localized lesion such as we are concerned with in the following cases.

REPORT OF CASES

CASE 1. E. K., a twenty-three year old male Jewish salesman entered the Boston City Hospital November 11, 1934 complaining of pain in the lower left chest, left shoulder and also of diarrhea.

On the afternoon of August 20, 1934, after playing golf and tennis, the patient experienced a slight chill. He vomited that evening and perspired freely during the night. There were two chills each accompanied by a high fever during the next forty-eight hours. The bowels at this time were constipated. On the second day of his illness he developed pain in the left upper quadrant of the abdomen and in the left chest. The pain was made worse by breathing. At the same time he experienced pain in the left shoulder. There was nothing significant in the past history except for the fact that he had

been treated for a duodenal ulcer, but had been free of symptoms from this condition for one year

The patient entered the Lucy Hastings Hospital at Manchester, N H, on August 22, 1934 At this time the positive findings in the physical examination were dullness in the left lower chest over an area both front and back from the seventh rib down wards The abdomen was distended and tender throughout, but especially over the left upper quadrant where there was also voluntary spasm Palpation of this region was unsatisfactory for any tumor mass because of the pain produced by pressure

For the first three days after admission to the hospital the patient had severe chills each day, followed by profuse perspiration. With the chills the temperature rose to 104° or 105° The heart rate was 80 to 100 per minute About the third day he developed a diarrhea which lasted for about two weeks The patient remained in the hospital forty-one days, complaining at intervals of pain in the left upper quadrant of the abdomen and in the left chest

FIGURE 1
Chart of temperature heart rate and respiration in Lucy Hastings Hospital

After leaving the hospital he was fever free and without pain for about ten days He gained twelve pounds in weight and felt generally stronger Six days previous to the admission to the Boston City Hospital he experienced a more or less continuous pain of a low grade in the chest just to the right of the sternum in the 4th interspace This has persisted until now He had a return of the diarrhea, which lasted two days About four days previous to his entry to the Boston City Hospital he again experienced the left upper quadrant pain and had a fever of 102° F Since then he has been running an afternoon temperature The white count was 11,000 per cu mm of blood

The significant laboratory data were as follows On August 22, 1934, the examination of the urine was negative except for the presence of a slight trace of albumen The red count was 4.8 million and the white count was 15,000 per cu mm The differential white count contained 86 per cent polymorphonuclear neutrophils, 11 per cent lympho-

cytes and 3 per cent eosinophiles On August 23, the blood culture showed Gram negative motile bacilli, and blood cultures on future dates showed the same organisms The Widal test of the blood was negative on several occasions, and a blood test was also negative for undulant fever On September 8, blood culture were reported as negative for paratyphoid A and B On October 30, x-ray examination was negative except for a high diaphragm on the left side as shown in figure 2

FIGURE 2
X-ray of the chest demonstrating high left diaphragm

On entrance to the Boston City Hospital on November 11, 1934, the patient showed the following pertinent findings The skin was pale and dry Over the left side of the chest, posteriorly below the 9th space, there was flatness with absence of tactile fremitus, whispered voice, and breath sounds The area of flatness was higher in the axilla. Anteriorly there was dullness to flatness below the 5th rib and a definite friction rub was heard on inspiration in the anterior axillary line Over this area there was tenderness on percussion The radial pulse was rather small and collapsible and the arterial pressure was 114/76 mm Hg The abdomen was distended and tender, but without spasm except that of a voluntary nature in the left upper quadrant

The culture and Widal test of the blood was negative The red blood count was 4.3 million and the white blood count was 10,000 per cu mm of blood The hemoglobin content was 61 per cent Examinations of stools were negative for tuberculosis, motile amoebae and cysts X-rays of the chest showed the left diaphragm markedly elevated and flattened The outer half of the diaphragm was fixed The medial half moved slightly on respiration The right diaphragm was normal X-ray examination of the gastrointestinal canal revealed the stomach displaced toward the midline, and the splenic flexure of the colon slightly displaced downwards Flat x-ray plate of the abdomen (figure 3) showed an indefinite area of density in the left upper quadrant These x-ray findings were interpreted as being consistent with those of a left subdiaphragmatic abscess

In view of the fact that the diagnosis of abscess of spleen of unknown etiology was made operation under gas-oxygen-ether anesthesia was performed on November 22 1934. Incision was made in the

FIGURE 3.

X-ray of the abdomen revealing an indefinite area of density in the left upper quadrant.

left upper quadrant of the abdomen. Exploration of the latter was entirely negative except for the region of the left upper quadrant. The spleen was considerably enlarged. There were numerous ad-

FIGURE 4.

Showing a large postoperative sinus cavity filled with lipiodol.

hesions in the splenic region. On separating some of the adhesions and mobilizing the upper portion of the spleen an abscess cavity was found posterior to and involving the upper pole of the spleen. This cavity contained about six ounces of a watery pus

without odor. A cigarette drain was inserted into the abscess cavity and brought down around the outer border of the spleen and through a stab incision under the left costal margin. The original incision was closed without drainage. The patient was transfused with 500 cc. of citrated blood. The drain was removed on the twelfth day. A catheter was then placed into the sinus tract. Through this irrigations of salt solutions were carried. From time to time the question arose as to whether the sub-diaphragmatic space was being sufficiently drained. However the profuse discharge diminished and the patient left the hospital on December 27 1934 thirty-six days after operation with the catheter still in place. Lipiodol studies of the sinus tract made on December 20 1934 are shown in figure 4 indicating a large sinus cavity. Similar studies made on February 6 1935 are shown in figure 5 and demonstrate healing of the cavity with a narrow tract filled with lipiodol.

FIGURE 5.

Showing healing of the cavity with narrow tract of lipiodol in the left upper quadrant.

After removal of the catheter the sinus tract gradually healed. The patient's health has been perfectly normal to date. Figure 6 shows the clinical chart while the patient was at the Boston City Hospital.

Bacteriological studies of cultures of the pus removed from the abscess cavity demonstrated that the sugar fermentations were identical with those of the American and European type of *B. suis*. H₂S was not found in lead acetate agar, which permitted a presumptive diagnosis of the American type. Bacteria were agglutinated by a 1:2560 dilution of an anti-American type serum which agglutinated a stock American type strain in a dilution of 1:1280 and a stock European type strain in a dilution of 1:40. The etiological significance of bacilli which were isolated from the patient is proved by the fact that they were agglutinated by a 1:1280 dilution of his serum but were not agglutinated by dilutions of several normal sera as low as 1:40.

The unusual features of the case are as follows (1) A healthy individual suddenly seized with symptoms of a gastrointestinal nature, but with no history of food poisoning (2) The clinical course was similar to that of a paratyphoid infection (3) Blood culture showed a Gram-negative motile bacilli, negative for typhoid and paratyphoid A and B (4) Clin-

CASES REPORTED IN THE LITERATURE

Stimulated by the above-mentioned cases, we reviewed the literature to date with reference to surgical lesions associated with the *B suispestifer*. As will be seen almost all the cases were in children. We were able to gather the following cases

FIGURE 6
Chart of temperature heart rate and respiration in Boston City Hospital

ical evidence of splenic abscess appeared and on surgical drainage the infection, after bacteriological study, proved to be due to the *B suispestifer* of the American type

CASE 2 The second case from the records of the Boston City Hospital is as follows. A colored female, aged forty, entered the hospital on June 3, 1934, for treatment of diabetes mellitus. During the course of the hospital stay it was discovered that she had a positive Wassermann test of the blood. Her history also indicated that there was a possibility of a chronic cholecystitis. The Graham test confirmed this diagnosis. On June 5, 1934, a cholecystectomy was done. The gross findings of the gallbladder were not remarkable other than showing evidence of chronic infection. The microscopic finding was that of chronic cholecystitis without stones. Cultures from the gallbladder showed a Gram negative bacillus.

Bacteriological study of this case also showed sugar fermentation tests identical with the American European type and also failed to form H_2S . However the bacilli in this instance were not agglutinated by anti American type serum but in view of the biological reaction, the tentative interpretation of a nonagglutinable strain of the American type was made.

The patient has had several subsequent hospital reentries for the treatment of diabetes but without symptomatology that could be attributed to the proved *B suispestifer* infection. Agglutination tests for *B suispestifer* types have not as yet been done on the patient's serum.

(CASE 1) Reported by Nabarro and White. This was of a child nine months of age who had been ill for two months without a definite diagnosis having been made. Attention was finally focused upon the right shoulder as possibly being infected. Aspiration of this joint showed a thin fluid. Bacteriological study revealed the organism to be that of the American type of *B suispestifer*. The patient was cured by aspiration of the joint. Apparently this is the first reported case either medical or surgical of the American strain of *B suispestifer* being found in Europe.

(CASE 2) The same authors incidentally mention but do not report in detail another case of a joint abscess in a child due to the European strain *suispestifer*.

(CASE 3) Kuttner and Zepp report a case of a male Negro child, nineteen months of age, who after complaining of malaise for two months developed a swelling of the right knee. The white count was 28,040 per cu mm of blood with 64 per cent polymorphonuclear leucocytes. Aspiration of the joint and bacteriological study of the pus revealed *B suispestifer* of the European type. The patient was cured by aspiration of the joint.

(CASE 4) The same authors report a second case of a female, aged five months. The first symptom was that of inability to move the right arm. The right shoulder joint finally became swollen. X-rays showed some destruction at the head of the right humerus. The white count was 22,600 per cu mm. of blood with 56 per cent polymorphonuclears. Aspiration of the joint showed pus. Study again showed the organism to be *B suispestifer*, European type. The patient was treated successfully by immobili-

zation of the right shoulder joint. This case demonstrated no febrile reaction during the illness.

In addition three other instances of localized lesions due to the *suppustifer* should be mentioned. However the details regarding the bacteriological study of the cases are not available.

(CASE 5) Gazzégo and Göttsh report a case of osteomyelitis due to the *B. suppustifer*.

(CASE 6) Tevell cites a case of pyarthrosis of the shoulder joint due to the same organism.

(CASE 7) Bruin and Janssen report a case of infection of the knee joint the organism being the *suppustifer*.

It is quite evident from the cases observed by us and from those reported in the literature that the surgical lesions developing during the human *suppustifer* infections are similar in distribution to those found as complications developing during typhoid and paratyphoid disease.

Inasmuch as attention has only recently been focused upon the human infection due to the *B. suppustifer*, it is not unlikely that cases in the past attributed in a general way to the paratyphoid group could well have been due to the *B. suppustifer*, but because of the inadequate bacteriological studies were not accurately classified.

SUMMARY

1 Two cases with localized surgical lesions due to the American type of *B. suppustifer* are reported. In the first case following a transient bacteremia, a metastatic splenic abscess developed, causing the clinical picture of left subdiaphragmatic abscess. Surgical drainage of the splenic abscess relieved the patient. In the second patient, *B. suppustifer* was responsible for cholecystitis with the usual clinical course.

2 In spite of the fact that both cases reported were adults, *suppustifer* infections in man have been reported most commonly in babies and children.

3 Unless serological and bacteriological studies are complete, many of the lesions associated with the *B. suppustifer* will be attributed to some unidentified Gram negative motile organism.

4. Localized surgical lesions associated with the *B. suppustifer* are rather rare and they are similar to the surgical complications of typhoid and paratyphoid fever.

5. *Suppustifer* abscesses, in the majority of instances, occur probably as the result of septicemia, secondary to a gastrointestinal infection due to contamination of food with the *B. suppustifer*.

DISCUSSION

DR. GILE, Hanover N. H. Our experience with surgical complications of salmonella *suppustifer* have been nil and the literature seems to have few reports.

Park and Williams say "Quite a number of paratyphoid varieties have been found to be the causative agent in food infection. Three paratyphoid varieties however have been the most frequent causative factors. Members of the *B. pestis* cynine (that is the guinea pig bug) or *Bacillus aertrycke* for one, *Bacillus suppustifer* and *Bacillus enteritidis*. These are the three general subdivisions of the paratyphoid that are particularly food infectious organisms.

The bacilli may invade the blood stream and may find their way to the urine. This is most likely to be so in fatal cases."

Perhaps this is an example of localization in this case after a blood stream infection and abscess formation in the liver.

Quoting from Ford, "Speaking of intravenous infection of rabbits, a perfect serous exudate is found in the large body cavities with a fibrous deposit on the serous membranes, often containing small hemorrhages. Spleen and liver enlarged and show small circumscribed necrotic foci which may resemble the lesions in tuberculosis. Outspoken lesions of the intestines and patches in the lungs resembling bronchopneumonia may also occur. With large animals cattle, goats, etc. subcutaneous injection is followed by large localized abscesses and intravenous injection produces severe general reaction.

This whole group of paratyphoid organisms are subject to very evident variation. "Kendrick has observed that variants of *Salmonella enteritidis* may be derived from smooth and rough forms by the action of bacteriophage." This is additional evidence to me anyway that we do get very decided variations in this group of organisms, from motile to nonmotile and even capsulated forms. There must, of necessity, be very distinct variations in the pathogenic proclivities of these organisms.

Quoting from Zimner and Bayne-Jones, "Paratyphoid B. is probably a more common disease than paratyphoid A. and is more apt to be typhoid like and severe.

From the very distinct differences between the clinical manifestations of this disease and the ordinary case of so-called 'food poisoning' it would appear that there must be a very definite human paratyphoid B. organism which is conveyed by the same agencies and subject to the same epidemiological laws as typhoid fever. It is difficult to base this on bacteriological evidence since it is often impossible to find any cultural or agglutination distinctions between organisms isolated from the human blood or bowel and other bacilli which from their sources and general reactions would fall into the groups of hog cholera, enteritidis, etc."

Another sentence on the same page "It is difficult always to be certain that the strain is a true *Bacillus paratyphosus B.* and not *Bacillus aertrycke* or some closely related variety.

Another sentence, "The organism called *B. paratyphosus C* which was responsible for many cases of paratyphoid fever during the War has been identified by Andrews and Neave as one of the types of *Bacillus suppustifer*.

It was formerly believed that hog cholera was

due to the bacillus which bears this name" "Since then it has been found that this disease is due to a filtrable virus. The constant presence of this organism in animals suffering from this disease, is, therefore, something of a mystery, but is probably due, as Dorset has suggested, to the fact that the organism is a constant inhabitant of the intestine in hogs, and manages to get into the circulation as a consequence of the pathologic conditions incident to hog cholera. A similar association of organisms in blood cultures with diseases of which they are obviously not the primary etiological factor has been observed in other conditions, notably, for example, the Plotz bacillus in typhus fever"

From the above brief review of the literature it can be seen that these groups of organisms are fairly prevalent and from the statements it can be seen that they may and doubtless are the cause of more surgical complications in man than we have been aware, particularly when we consider various cultural characteristics and the difficulty in isolating them

In each of the past two years in routine examinations of all freshman stools, a considerable number of paratyphoid carriers are found and it may be that more careful cultural methods will produce more cases of the type about which Dr Walker has given so careful a report in his paper today

CANCER OF THE MOUTH CARE OF THE PATIENT UTILIZING PROLONGED ANESTHESIA OBTAINED BY ALCOHOL INJECTION OF BRANCHES OF THE FIFTH NERVE*

BY HUGH F HARE, M.D.,† JAMES L POPPEN, M.D.,† AND WALTER B HOOVER, M.D.†

THE purpose of this paper is to present a method of caring for patients with cancer of the mouth wherein the alleviation of pain is of prime consideration. The alleviation of pain in patients with oral cancer has received too little attention, but we believe it to be an extremely important consideration because the dread of severe pain and the reaction following radon application have become almost as great in the minds of the laity as the fear of pain and deformity associated with surgical treatment. We further believe that if pain were eliminated in every patient, the dread of treatment in the mind of the layman would be diminished and the tendency to seek early treatment would be greatly increased. It is true that most patients with this type of lesion, having presented themselves for treatment, are cooperative and are willing to go through a period of discomfort. Many, realizing the severity of either radon or surgery, hesitate to seek or receive advice.

Since Dominici¹ in 1910 first described the removable radon needle, radiological treatment of cancer of the mouth has gradually become the method of choice. During the past twenty-five years, great improvement has been made in the estimation of adequate lethal dosage for various tumors, in the filtration of undesirable radiation and in the protection of uninvolved tissues. We now feel fairly confident that the lethal dose may be quite accurately estimated for a given type of tumor and also the amount of filtration necessary to prevent a severe grade of reaction.

When we consider that treatment by the most skilled has failed to cure more than one in three or four of these patients with oral cancer, together with the pain and expense involved, it is readily understood why many are discouraged and do not seek advice early.

We believe a definite diagnosis should be established by biopsy without fear of dissemination of the cancer cells, if sealed by cautery or if followed by adequate treatment. When a diagnosis is established, the patient or a responsible relative should be told of his condition and the course of treatment be thoroughly explained to him. This explanation produces a more cooperative patient. In treating oral cancer, more than elsewhere a cooperative patient is necessary. With the patient having a knowledge of his condition and an idea of his course resulting from treatment, we are ready to proceed.

In the Clinic, numerous cases of trigeminal neuralgia and some cases of advanced cancer have been relieved for twelve to fourteen months by an alcohol injection into the second or third divisions of the fifth cranial nerve. It occurred to us that alcohol injection would be a valuable procedure to use before radon treatment in cancer of the mouth. Accordingly, during the past year, we have used this procedure routinely with most satisfactory results. The method of injection will be described later.

THE ADVANTAGES OF PROLONGED ANESTHESIA

1 Prolonged anesthesia permits ambulatory treatment of the patient, obviating the constant, dull, nerve-wracking pain usually accompanying caustic radon treatment. Free of pain, the patient is able to carry on with a portion of his duties without great difficulty.

2 The patients are able to sleep and rest comfortably without opiates or strong sedatives.

3 Oral hygiene is improved. The patient can cleanse the mouth without pain, for this reason, the cleansing is more thorough and secondary infections accompanied by fetid breath less common.

4 The patient can eat without difficulty and without discomfort, except for numbness on the affected side. Without pain and nauseating drugs the appetite remains fair and the loss of weight which usually occurs with treatment has become negligible.

5 Radon implantation may be done without further anesthesia. The patient being cooperative, more accurate placing of each radon seed is allowed in and about the lesion.

6 The anesthesia allows the patient to wear a lead shield to protect the uninvolved tissues of the mouth for the first two weeks after radon implantation with little discomfort. The shield may be made larger than could ordinarily be tolerated, the larger shield giving more protection.

The disadvantages of the injection are minor. The patients complain of various paresthesias such as numbness and prickling sensation of the anesthetized side.

CARE OF THE MOUTH

In noninfected cases, no special care of the mouth is indicated before radon implantation. In the secondarily infected lesions, we believe that obvious sources of infection such as carious teeth should be cleared up and that a series of deep x ray treatment should be given over the affected side. The dose should not be larger than 3000 R units given in fifteen treatments as we must not injure the skin or subcutaneous tissues when radical resection of the glands of the neck is to be carried out later. During the time of the x ray treatments, hourly mouth washes of table salt should be used and the lesion carefully cleansed with a moist cotton pledget. This will decrease the infection about the lesion in from four to six weeks' time preparatory to placing the radon. We feel that the use of tobacco has been definitely demonstrated to be harmful and should, without question, be prohibited in all forms irrespective of the type of treatment to be administered.

Immediately before radon implantation is performed, the mouth should be thoroughly cleansed with seventy per cent alcohol, other antiseptics are unnecessary. After the radon implantation, hourly mouth washes of salt solution are advised for a period of two weeks and then six times daily. Gradually, the frequency of mouth cleansing is decreased as the lesion and reaction disappear.

PROTECTION OF THE ADJACENT TISSUES

A shield made of lead foil, 5 mm thick, smoothly coated with dental compound, should be prepared before the radon implantation and carefully fitted to the mouth. To be effective the shield must be of sufficient size to protect the structures adjacent to the lesion which is to be implanted with radon. In lesions of the tongue, this shield should be made large enough to cover the mandible on the adjacent side and the roof of the mouth. In cases where the floor of the mouth is involved, it has been suggested by one of us that in order to protect the mandible, it would be wise to separate the gum from the mandible and place the lead foil be-

tween the gum and the bone. This can be performed without discomfort due to the anesthesia and will be tried in the next case requiring this protection.

The lead shield should be used for two weeks which is the time of major radon activity and it should not be removed except for cleansing and feeding.

FEEDING

Liquid food of high caloric content is all that is required during the period of intense reaction. Our patients are given such a diet and solid foods are gradually added until the patient is able to take a normal diet.

TYPE AND METHOD OF INJECTION

Lesions of the tongue, the floor of the mouth, the mandible, and lower portion of the cheek are in the area supplied by the mandibular or third division of the fifth nerve. In such cases, an alcohol injection of the third division of the nerve is employed on the affected side.

Lesions which involve the hard palate and anterior three-fourths of the soft palate together with those involving the maxilla or upper cheek lie in an area supplied by the second division of the fifth nerve. Therefore this division is injected with alcohol on the side affected by such lesions. Cancer involving the areas of both the third and second divisions require injection of each.

Sensation to the posterior margin of the soft palate, the posterior portion of the tongue, the tonsillar fossa, and the pharyngeal walls is supplied by the glossopharyngeal nerve. Figure 3

FIGURE 3. Demonstrates the cutaneous anesthesia following the injection of alcohol into both the mandibular and maxillary divisions at their exit from the cranium. The amount of overlapping of the cervical nerves over the ramus of the jaw varies in different individuals.

illustrates the sensory distribution of this nerve. Although we have never performed a neurectomy of the glossopharyngeal nerve to relieve

FIGURE 2 The lines indicate the distribution of anesthesia of the third division inside of the mouth. The dots demonstrate the maxillary division. FIGURE 3

pain in treating cancer cases, it has been practiced by others for relief of pain and may well be worthy of consideration in selected cases

Before alcohol injections are attempted, one

must have a thorough knowledge of the skull with relation to the structures around the axis of the nerve trunk. This can be obtained only by dissection of the head and neck as well as by injecting the nerve trunks in cadavers with colored solutions in this way becoming familiar with the bony landmarks and approximate depth of foramina rotundum and ovale. After one has become acquainted with the landmarks, it is important if possible, to see injections performed by someone who has had experience with the procedure and likewise, do injection on patients under supervision. A most important faculty to develop is that of being able to visualize deep structures in three dimensions.

For the actual injection, a small instrument bag is all that is necessary. This consists of a five cubic centimeter Luer-Lok syringe, two No. 22 gauge needles three inches long, a centimeter,

FIGURE 4

measure, a hemostat, a prepared solution of eighty per cent alcohol containing one per cent novocaine and a little bone wax to use as a marker on the needle. For all injections, the patient is asked to lie flat on the back on a table of sufficient height where the operator can be in an easy position. For a deep injection of the second and third division, the patient's head is turned well over to the opposite side and rests on a sandbag about two to three inches in thickness. We find that one-fourth grain of morphine given an hour before the injection will give us a more cooperative patient.

It is not necessary for the operator to clean up or use rubber gloves in giving injections, a manner to which we have become accustomed. The preparatory routine is as follows:

The sterile injection set is opened and with the sterile hemostat contained in the set an appropriate needle is adjusted to the syringe. If an injection of the foramen rotundum or ovale is contemplated, a bit of bone wax is fixed

around the needle, one centimeter beyond the usual depth at which these structures are reached. Two cubic centimeters of the eighty per cent alcohol mixture is drawn into the syringe, after which the appropriate area on the patient's cheek is sterilized with seventy per cent alcohol. A small piece of gauze dampened with alcohol is placed over the area to be injected in order that landmarks may be palpated through this. The approaches which we use to the foramen ovale and foramen rotundum are essentially the same as those described by Hartell and Harris.

Third division injection. For this procedure the bone wax marker should be placed on the needle at a distance of 5.5 cm. from the point thus giving 1 cm. leeway between the marker and the depth at which the nerve should be reached. The syringe with attached needle is taken in one hand while the index finger of the other palpates through the sterile gauze the highest point of the notch on the lower border of the zygomatic process. The patient is then instructed concerning the procedure by being told that there will first be a slight prick as the skin is pierced after which no great discomfort will be felt until the nerve is entered when there should be experienced a pain sharp in character, radiating down the lower jaw to the chin or to the front of the tongue. The patients are told particularly to let the operator know if pain radiates upward into the temple or backward toward the ear because when the radiation occurs in these directions, it means that the needle has impinged upon the meningeal artery, the eustachian tube or the auriculotemporal branch of the third division.

The sterile gauze is now removed from the cheek and the needle inserted just below the zygomatic notch at the point where a slight imprint will have been left by the palpating finger pressed upon the gauze. The needle is directed slightly upward and backward and at the depth of four and a half centimeters, the nerve trunk may be reached upon the first attempt. If pain radiates correctly, a drop or two of alcohol is injected. This causes a momentary severe pain over the course of the nerve, but it is followed immediately by numbness and cessation of pain. If the nerve is not reached at the usual depth our practice is to withdraw the needle a centimeter or two and then direct it somewhat forward so as to come down upon the external pterygoid plate. This is an essential landmark because the foramen ovale lies just posterior and slightly medial to it. With disorientation the needle is again withdrawn somewhat and directed a little backward until the nerve is entered as evidenced by a pain radiation. It may be necessary to repeat this process several times and also it must be remembered that there are slight variations in the depth at which the for-

men lies. In some individuals, it may be reached at slightly less than four and one-half centimeters and rarely at a depth as great as five centimeters from the skin.

When the nerve trunk has been entered and a few drops of alcohol injected, the patient's lower lip near the median line is tested for anesthesia. This should be done with a pin point and the patient's eyes should be closed. If a fair hit has been made, the sensory loss is almost immediate on this portion of the lip, lower gum and half of the anterior two-thirds of the tongue. Having determined this, we then inject about 1 cc of alcohol very slowly after pushing the needle gently inward for a millimeter or two during the process, in order to be sure that the substance of the nerve is wholly injected. The needle is then withdrawn and pressure made over its point of entrance with sterile gauze in order to prevent oozing. The patient is now asked to open the mouth. If injection of the third division has been complete, the lower jaw will deviate distinctly toward the affected side.

One further point regarding the injection should be noted. At times when the needle is in the proper position and depth, there is no radiation of pain down the jaw, but severe pain is present at the tip of the needle. This happens in a fairly large percentage of cases. A drop of alcohol may then be injected and it usually brings on radiation of pain followed by numbness indicating that a fair hit has been made. The reason care should be taken in injecting only very small amounts slowly, is that at times the point of the needle enters the foramen ovale unwittingly. If the point happens to be in the subarachnoid space around the ganglion and alcohol is injected, severe reactions as well as permanent damage may be done. If on the other hand, only a drop has been injected and if the patient develops nystagmus, vomiting or other untoward symptoms the needle should be withdrawn. The resistance with which the alcohol enters is usually a reliable indicator as to whether the needle is in nerve tissue provided, of course, that the position and depth are proper as well as the definite radiation of pain. Should the patient complain of severe pain in the ear, as the injection is started, it may mean that the alcohol is entering the eustachian tube or has struck a small branch of the trigeminal which innervates the ear.

Second division injection. The patient is prepared in the same manner as for the third division. The needle is pressed through the skin just beneath the anterior portion of the zygoma and anterior to the coronoid process. The needle passes medially at a forty degree angle anterior to the coronoid process and immediately posterior to the maxillary process. This is

the so-called "anterior approach" As it enters the pterygoteigomaxillary fissure which is a narrow opening about 5 cm wide, it usually strikes the external pterygoid plate behind the posterior border of the maxilla in front. The nerve, as a rule, is reached at $5\frac{1}{2}$ cm depending, of course, on the width of the face of the patient. It is important that one should not go deeper than six centimeters at any time because of possible injury to important structures, especially the optic nerve. If the external pterygoid plate is struck, it can be used as a valuable landmark, the foramen rotundum lying anterior and 75 to 1 cm deeper. If the posterior portion of the maxilla is reached before entering the pterygomaxillary fissure, it will also serve as a guide keeping in mind that the fissure in which the nerve lies is founded by the maxilla anteriorly and the external pterygoid plate posteriorly. By gentle manipulation of the needle, the nerve will be reached if no unusual bony prominence makes it impossible. Throughout the procedure, one should have a mental picture of the deep structures. As soon as the needle enters the nerve tissue, a spray of pain will be felt along the course of the nerve. Here, again, only a few drops of alcohol are injected at a time. If complete anesthesia of the upper lip, ala of the nose, and roof of the mouth is obtained, one or two cubic centimeters more is then injected slowly. The most reliable place to test the anesthesia obtained is on the upper

lip and the ala of the nose while the patient has the eyes closed. There are no contraindications to alcohol injection with the exception of local infection in the skin or tissues through which the needle must pass.

CONCLUSIONS

The relief of pain during treatment for oral cancer is of prime consideration.

Our method of utilizing prolonged anesthesia, and the method of producing it by alcohol injection of the 2nd and 3rd divisions of the fifth nerve have been described.

In addition to relief of pain, this prolonged anesthesia is advantageous because

- 1 It allows the patient to wear the necessary protective shield more comfortably.
- 2 The mouth is easier to cleanse.
- 3 The loss of weight during treatment is negligible as the patients are able to eat well during the period of intense radon reaction.

THE PSYCHOGENIC PROBLEM (ENDOCRINAL AND METABOLIC) IN CHRONIC ARTHRITIS*

BY H ARCHIBALD NISSEN, M D,[†] AND K A SPENCER[†]

IT is with interest that a medical internist addresses a group of psychopathologists. He brings to you for solution some of the clinical observations of the individual, the chronic arthritic. These observations have been checked repeatedly, and today are presented to you for consideration and opinion. Whether cause or effect, accident or coincidence, related or unrelated symptoms and signs of joint impairment without demonstrable infection, toxemia, etc., the single constant is disturbance of the psyche and homeostasis. What is the answer? The practice of medicine, especially "chronic" medicine, emphasizes the well-known fact that no one specialist can succeed without the other. Today this is particularly true of the internist and the psychopathologist, or psychiatrist. Both practitioners realize the importance of the psychogenic and endocrinal (metabolic) factors in

chronic disease. The internist, however, in dealing with the psychical, feels he is leaving the realm of pure science and entering that of theory and belief, whereas the psychopathologist, by successful application of therapy along psychological and endocrinal lines, knows he has changed surmise and theory into fact. Years of study of the clinical course of a group of patients with chronic disease, especially that called arthritis, brings one to the conclusion that the psychical affects the clinical picture to a great extent. The internist recognizes this fact but can go only a limited distance in treatment before he realizes that one better equipped than he is needed. In short, if the chronic disease patient is to be treated adequately, a close relationship between internist and psychopathologist must be established and maintained.

The term *arthritis* is applied loosely to any and every complaint referable to a joint*. Actually about thirty-five per cent of patients with so-called arthritis, seen in practice, will prove

*Read by invitation before the American Psychopathological Association May 18 1935 in Washington D C

[†]Nissen H Archibald—Member of the Staff and Visiting Physician New England Deaconess Hospital. Spencer K A—Medical Research Statistician. For records and addresses of authors see This Week's Issue page 596.

*Naturally acute traumatic or septic surgical joints are excepted.

to be suffering from that disease. Of this thirty-five per cent a certain number will be found to have a specific arthritis,—gonorrheal, luetic or tuberculous. The remainder, possibly twenty-five per cent of the original number will be genuine arthritides of unknown etiology. (In a recent study the authors found that sixty-eight per cent of a group of five hundred arthritides were in fact patients with degenerative or tissue changes, and only thirty-two per cent had arthritis, i.e., actual joint destruction. The destruction may be partial or complete but a certain amount is definite. Tissue changes, contraction or atrophy of muscles, may cause deformity, but arthritis is not necessarily present.) This genuine arthritis has been classified variously as "rheumatoid", "Type I", "infectious", "atrophic", or "arthritis deformans". To some, including the authors, it is simply arthritis of unknown etiology. To others its etiology is definitely considered as streptococcal in origin. One of the most reasonable exponents of this belief is Hindley Smith.² He considers joint involvement of this type merely one symptom of a definite disease which he calls "chronic streptococcal toxæmia". His description of this condition resembles Coburn's³ "rheumatic state". Keefer⁴ on the other hand does not agree that the theory of focal infection as the etiologic agent in arthritis has been proved. In any case whatever the etiology of this non-specific arthritis, its sufferers are the patients for whom the physician can do the least in the way of arresting the disease or improving the general condition. They are the individuals, many of whom following a Life Course C⁵ become and remain crippled in varying degrees. They present a tremendous medical, social and economic problem in practically every civilized country.

In the accepted classifications of arthritis gout is the only type listed as a "metabolic joint disorder". (There are those who consider the degenerative changes occurring in women at the climacteric as being also metabolic in origin.) Many facts suggest that this non-specific arthritis is another metabolic (endocrinal) disturbance. Cannon⁶ has proved the effect of emotional states on the homeostasis, and eventually on the physiology, of the body. He applies the term "homeostasis" to the normal correlation and functioning of the different body systems, and demonstrates the effect on them of uncontrolled emotion, particularly of rage and fear on the endocrinal glands. These same emotions, and in man their intermediates, strain, grief, etc., thus disturb the mechanism regulating the distribution of sugar, calcium and other mineral constituents, fluid retention and excretion, blood circulation and the autonomic nervous system. Obviously prolonged disturbance of any one of these is likely to produce physiological change.

As early as 1919 Jelliffe and White⁷ discussed "bone disorders due to disturbances of nervous functioning". They attributed to "certain hypothyroidisms" the development of a rheumatoid arthritis possibly by reduced capacity of the individual to react normally to minimal subinfections.⁸ They concluded their observations as follows: "Psychogenic arthropathies and arthritides are as yet not definitely established. There is some evidence from the psychoanalytic school to show that unconscious complex reactions may show themselves as bony syndromes. The classical relationship between excessive anger and gout is a case in point. Unconscious sadistic states produce transitory and even chronic arthritic changes." In the sixth edition of their work⁹ the same observations are amplified. One reads "The psychogenic discipline is also commencing to show that purely emotional reactions extend deep down in the individual's metabolic processes and must be evaluated in the study of chronic arthritic processes." "It is here considered absolutely imperative that such factors" (psychogenic) be evaluated in the study of some of the arthritides."

Richardson⁸, Stokes¹⁰ and others have observed psychopathy in its relation to physiological changes and organic disease. The authors believe that psychogenic factors play an important etiologic role in the production and maintenance of the nonspecific arthritic syndrome, though a review of the literature on arthritis will not show this to be a general opinion. Rivers¹¹ suggests it. Many writers include psychotherapy in the régime of reeducating a crippled patient. Some men cite worry, strain, etc., as contributory factors, but as a rule do not stress their importance. The psyche must be recognized also as a causative or activating factor in joint disturbances other than arthritis,—that is in those confined to capsule and soft tissue, or degenerative joint changes.

The actual association between psychical and physiopathological is as difficult to prove as that of the much debated focal infection and systemic involvement.¹² However, in spite of the incompleteness of most clinical case histories, and the paucity of detail, it is interesting to note how frequently a story of emotional stress precedes, or coincides with the onset of physiological dysfunction in the chronic disease patient. A follow-up study of a large group of patients will emphasize this point. In a yearly check-up repeated conversations with the same patient will elicit facts in the emotional life previously undisclosed. No first examination reveals the inner stress which may have been present in the early years of illness. (A relatively short hospital stay, without subsequent yearly follow-up, is of course responsible for the dearth of personal information in the usual hospital record.) In the authors' group of five

hundred arthritic patients, analyzed according to the functional life course each followed^{1, 5}, eight per cent of Courses A and D ("A" comprised of the best tissue and "D" of the worst), twenty-six per cent of Course B, and thirty-eight per cent of Course C gave a history of recognized psychical disturbance. In other words, twenty-two per cent of the five hundred could be classed definitely as having had sufficient emotional strain preceding the arthritic onset to warrant its being considered an etiologic agent (It is believed that given proper opportunity a similar story would have obtained from many others). In a previous article, one of the authors suggested the similarity between the schizophrenic and the arthritic¹³. Hoskins¹⁴ list of etiologic factors, potentially important in the schizophrenic, applies equally to the arthritic.

Emotional conflicts

Withdrawal of interest in environment and transfer to phantasy life

Bad mental and physical habits

Disturbed acid-base equilibrium

Vitamin deficiency

Infectious and surgical disease

Other metabolic disease

The chief point of *difference* between the two appears to lie in the outlet chosen for the emotional disturbance. The schizophrenic finds his escape from reality through fantasy or dream life, the arthritic through the somatic or physical. In a recent visit to a state hospital for mental diseases not a single arthritic was found among 2200 patients, while in the group of 500 arthritics analyzed only three were diagnosed as having mental disease. The arthritis in these cases was of gonorrheal origin and had left no great residual handicap.

The one hundred and thirteen patients out of the entire group of five hundred with recognized psychical disturbance showed forty-three per cent with nonspecific arthritis, seven per cent with specific arthritis (gonorrheal), twenty-four per cent with tissue changes, causing deformity in some, but without actual arthritis and twenty-three per cent with degenerative changes. Three per cent followed Life Course A (a course in which the patient returns to practically normal activity after recovery from the initial joint disturbance), fifty-two per cent Course B (the patient in this course shows remission and relapse of joint symptoms with no

marked disability until the terminal years of life) thirty-eight per cent Course C (the patient in this group shows a drop to a markedly subnormal level of functional activity in from one to seven years and remains at the low level the rest of life), and three per cent Course D (a steady, downhill progression without remission). Another unanswered question is why certain emotionally unstable individuals, if seeking escape from reality, followed Courses A and B, achieving only temporary release, while others followed Course C, securing permanent escape. Was the strain less severe, or the tissue inheritance and acquired intelligence better in the A's and B's than in the C's? The internist can only question, the psychopathologist may go farther and learn the truth.

In all the cases it seems reasonable to believe that the psychical maladjustment preceded the evidences of physiological dysfunction. In some instances the psychical element was alone sufficient to cause a slow, gradual metabolic change, eventually resulting in actual joint or tissue damage, in others, it caused the same metabolic change which was aggravated by individual receptivity (allergic sensitization) to infection, and in others or perhaps in all, there was the additional factor of poor tissue inheritance, tissue unable to cope with infection, or an inherited mental and emotional make-up too unstable to adjust itself to life's demands. In short, two factors stand out as vital in the etiology of certain arthritides, the mental or psychical reaction and the inherited body tissue. (Possibly both must be considered as inherited tissue if an individual inherits psychical as well as physical components. The psyche appears to be the necessary catalyst to maintain equilibrium between the physiological and functional activity of the body, but if these two activities are out of balance, the psyche is unable of itself to change the imbalance.) Nutrition during the first five years of life, and environmental influences, also play important parts.

REVIEW OF CASES WITH RECOGNIZED PSYCHICAL AND ENDOCRINAL DISTURBANCES

(Twenty-two per cent of the 500 studied)

Observation of psychical and metabolic disturbances do not lend themselves to the usual statistical tabulations, but a few figures are of interest. One hundred and thirteen patients out of the group of five hundred were known to have shown definite endocrinal and psychical disturbances with associated joint reactions, consisting of pain, congestion or swelling. As a rule no acute inflammatory joint symptoms or signs were present. In a few cases they were evident, but accompanying them were other toxic factors. Sixteen per cent of the group were male and eighty-four per cent were female. In the male group, joint disturbances followed marital upheavals, sudden violent shock, or re-

tirement from a long period of strenuous business life (removal of motivation for living without substitution) In the young women definite endocrinal disturbances were manifested by menstrual irregularities (fourteen per cent of the women in the group), definite association between menstruation and increased joint pain or congestion (seven per cent of the group) improvement in joint symptoms during pregnancy with relapse following delivery, etc. Twenty-two per cent of the ninety-five women in this particular group developed arthritic symptoms or had a flare up of former joint disturbance during menopause. In still older women whose arthritis began years after the menopause many showed a combination of cumulative infection and exposure, plus a sudden cessation of a former motivation for living a motivation which had carried them through the previous years of tremendous mental and physical strain.

Fifty-eight individuals (fifty-one per cent of the group) had a history of years of maladjustment, of emotional and mental strain of early implanted fear or of shock preceding the onset of arthritis. (Of these, eight carried an additional load of infection.) Six were men, fifty-two women.

Fifty-two patients (four men and forty-eight women) were of an emotionally unstable type. They had shown hysteria, mild phobias, nervous breakdowns and general instability under stress.

In forty-six patients (five men and forty-one women) there was recognized exacerbation of joint symptoms with emotional crises.

Three men and fourteen women showed marked weight fluctuations, eight men and twenty-four women showed tissue changes manifested by muscle congestion, contractures or atrophy.

Nine patients (three men and six women) improved with modified psychotherapy after other forms of treatment had failed. (This form of treatment had been tried in very few cases.)

In the "C" group, infection was marked in nine cases. These individuals dropped to their low level of functional activity rapidly, while the others, who showed no evidence of any infectious element, reached their low level gradually and more slowly. Also the duration of life after the arthritic onset was shorter when the extra load of infection was present. In other words, where the physical changes developed gradually over a period of years no infectious factor appeared to have been added to the accumulated psychical disturbance. The addition of infection and other extraneous elements to psychical imbalance, whether long drawn out or cataclysmic, produced an explosive physical response with a rapid production of joint and tissue damage and disability.

One or two illustrative cases will suffice.

A girl of unstable temperament at the age of fifteen was in a railroad accident. She developed

a "railroad spine" which eventually cleared up. Afterward minor accidents produced transient paralysis. She attempted to be a trained vocalist, found it too exacting and too difficult a career to pursue. She was unsuccessful in love. At the age of twenty-seven following a street car accident in which she suffered no bodily injury she developed gradually arthritic symptoms in all her joints. The joints were swollen and painful but not acutely red or inflamed. She was seen first five years after the onset. At the age of forty-two a condition of complete helplessness was present, fifteen years after the onset. At this time she presented a picture of infection (nasopharyngeal) plus a distorted motivation for living. She apparently obtained definite satisfaction in playing the rôle of a suffering martyr. She will talk about herself for hours as she lies in bed practically immobilized because of ankylosed and destroyed joints. A mother and sister are in constant attendance having been for years deprived of any normal life or activity which did not center about the patient.

Another patient, female, had been subjected to emotional strain from childhood. Her father deserted the family when the patient was five. The mother and children were deported from the United States back to Poland where they remained for the next five years, then returned to America. At sixteen the patient went to work in a factory (under poor hygienic conditions). At eighteen fleeting joint pains were noted. At twenty she was married to a man whom after marriage she discovered to be a manic depressive out on parole from a state hospital. Tremendous emotional strain followed. There was an arthritic flare-up after pregnancy a second after the next pregnancy a third after the death of the second child. This husband was in and out of asylums each parole ending in violence at home. The patient's joint exacerbations coincided with the periods her husband spent at home. She showed marked weight loss. Eight years after the onset she had become entirely helpless; ankylosis was present in every joint except a few fingers. There had never been acute inflammation of joints.

A third woman had been subject to recurrent severe infections all her life. Menstrual flow was always scanty. She was an only daughter. There were strong family ties. Shortly after her marriage both parents became chronic invalids due to cardiovascular disease, one with resultant motor disturbances and the other with cerebral changes. They and two brothers came to live with the patient, her husband and their one child a daughter. For the next twelve years the patient's home life was marred by emotional conflict and physical strain. Her susceptibility to infection and endocrinal dysfunction continued to be evident. Arthritic onset occurred at forty-five, menopause four years later. With the latter there was an exacerbation of joint symptoms. Following the death of the parents and lessening of emotional strain there was a definite subsidence of the arthritic manifestations. A year or more later relapse followed a new strain.

The patient's daughter was sixteen at this time. The patient attempted to reproduce her own experience, to dominate her daughter as she had been dominated. She capitalized her disability. Five years later with the rebellion of the daughter who left home secretly to be married the patient lapsed into a state of complete helplessness. Rapid deterioration followed. During her arthritic life there were recurrent periods of marked weight loss and gain.

During their various hospital admissions these patients were studied exhaustively by x-ray laboratory tests, and by consultation with otolaryngo-

logical, genitourinary, and gastro intestinal specialists. Only the nervous system remained unexplored. Only the individual personality, the psyche, was ignored. Only the man trained in psychopathology was unconsulted. The patients responded to no treatment which was tried. The only known form of treatment not attempted was psychotherapy.

PROGNOSIS

Five years or more must elapse after the onset of arthritis before one can make an accurate prognosis. During this time the patient is of course treated along accepted lines. Specific treatment, if indicated, rest, analgesics, supportive, dietetic and physiotherapy are carried on as well as orthopedic measures directed in prevention of deformity. To date, however, intelligent study and treatment of the individual personality has been inadequate. The potential arthritic, or the one seen first in the early stages of the disease, needs this just as definitely as he needs bed rest, diet or vaccines. The psyche calls for the care of a specialist as urgently as do the sinuses, the gastrointestinal or the genitourinary tracts. After the general practitioner has recognized his potential psychotic or arthritic, he must turn for help to the psychopathologist in order to reeducate and readjust the maladjusted psyche before physiologic or pathologic changes develop, before the combined problem of psychical and physiological disturbance becomes established. Too often psychotherapy is relegated to a place of minor importance in the routine treatment of an arthritic patient or is used only as a means of reconciling an established cripple to his life of inactivity. If this individual has consciously or unconsciously, reached his state of protected dependence purposefully, the application of psychotherapy at this point is too late. On the other hand, if this form of treatment is skillfully used in the pre-arthritic or early stages of the disease a future generation may see a marked decrease in the number of handicapped, or helpless, arthritics.

This paper contains a plea for help,—help that must come from other than the present avenues of research. It presents clinical observations plus personal follow-up for years of a group of patients with joint complaints, among whom are a certain number with real arthritis. These are not analyzable by the usual resources open to the practitioner of internal medicine. The psychogenic recognition calls for psychopathological help, and from this combination there may emerge,—first, a proved etiologic agent, and secondly, a practical therapy.

CONCLUSIONS

- 1 A certain number of genuine arthritics, in whom no reasonable, proved cause for arthritis can be found, is present in every group of so-called arthritics.

- 2 Among this nonspecific group will be evident numerous individuals in whom psychogenic and endocrinal disturbance has been dominant before and during the early stages of arthritis. This suggests that the etiology of this syndrome should be looked for in the psychical realm. Definite contributing factors are tissue and psychical inheritance, the first five years of life (nutrition and environment), exposure and infection, exogenous and endogenous. The psychical disturbances found in the group of patients studied were in some instances culminating affairs, or in others, long drawn out, constantly irritating emotional disturbances, which finally reached a point sufficient to disturb the body homeostasis. The individual involved obviously had no conscious recognition of the inside changes in physiology via the autonomic nervous system or endocrinal metabolic imbalance until the joints appeared as definite somatic evidence of such impaired function. Endocrinal disturbance in many was manifested by association between joint reaction and menstrual irregularities or menopause, by tremendous weight variations, by vasomotor changes, etc.
- 3 Endocrinal and metabolic physiology, plus the inherited psyche, represents an individual's birthright. If the birthright is sound, and the first years of nutrition are satisfactory, the individual will go through life in a philosophical manner without undue wear and tear on the psyche, or joint manifestations. However, if the individual inherits an unstable psyche and has poor nutrition during early life, with or without the addition of infection, he may be able to live and die without actual psychical or somatic disturbance, provided he finds a protected niche in life and escapes emotional and social strain. If, on the other hand, that individual has repeated rebuffs, suffers sudden or prolonged emotional strain, he may well be precipitated into schizophrenia or into an arthritic syndrome.
- 4 A striking similarity has been noted between a group of schizophrenic and arthritic patients. To date, genuine arthritis and schizophrenia have not been found present in the same patient. The objective of each is to escape reality. The schizophrenic achieves this by the mechanism of fantasy or dream state in its variations, the arthritic by somatic or physical pathways through functional disability.
- 5 These observations are based on a clinical follow-up of a group of arthritic patients over a period from four to eighteen years. There has been no jumping to conclusions. At the end of five years after the appearance

of joint symptoms a fairly accurate estimate of the future clinical course of the patient can be made

- 6 The internist can institute and carry on the physical treatment indicated, and can recognize the potential psychotic disturbance. He is limited in his application of psychotherapy however. A closer relationship between the psychopathologist and the general practitioner is urged as a means of solving the arthritic problem and so lessening the economic and social waste caused by it.

COMMENT

This paper was arranged primarily to present to a group of trained psychopathologists a problem of internal medicine, in which the internist realized his limitation in the treatment of rheumatism, or chronic joint disturbances. To any man in practice, specialist or general practitioner, similar observations of marked changes in motivation of living and emotional reaction in many patients must be apparent. To date the authors have yet to interview any man interested in rheumatism and allied rheumatic conditions, who did not admit to a certain percentage of failures, patients who had progressed steadily to complete destruction of all joints in spite of every effort. This paper offers a therapeutic aid to the man who will give sufficient attention to the psychological aspects of the chronic arthritic, particularly in the early stages. It is a measure which has been neglected. One of the most recent publications on arthritis¹³ does not contain in its index the words psyche, psychiatry or psychogenic. The physician who wishes to utilize psychotherapy has two alternatives, first, to apply it himself or secondly to

call in a consultant. The first means he must know enough of the function of the thalamus and hypothalamus, the endocrines, body metabolism and psychogenic manifestations, to apply this knowledge in his practice. If he does not not know, he must learn. The second alternative is to recognize his emotionally unstable patient (his potential arthritic) and to call in consultation, and work with, a psychiatrist if one is available. He must select, however, a man broadminded enough to be interested in applying his specialty (psychopathology) and no more to one group of patients (arthritis in this instance) over a period of years.

AN UNUSUAL FRACTURE OF THE LOWER END OF THE RADIUS

(Atypical Colles's)

BY DUNLAP P. PENNHALLOW, M.D.*

THE following case is reported as showing what is believed to be a rather unusual type of fracture of the lower end of the radius. This fracture on first inspection appeared to be a typical Colles's fracture but on closer inspection several dissimilarities, which will be explained more fully in the description, were noted. The nearest approach to this fracture which I have been able to find is one described in Seudder's *Fractures*, figs 714-715. That fracture is described as a T fracture of the lower end of the radius, in which there is no lateral displacement of the radial styloid although there is backward displacement of the lower frag-

ment. In the fracture about to be described there are several differences.

CASE. J. F. aged thirty-four white engineer. Patient states that while cranking an automobile engine, the engine backfired and the starter handle struck his right wrist causing immediate pain and disability. He was seen shortly after the accident and on first inspection appeared to have a typical Colles's fracture. There was the characteristic "silver fork" deformity and broadening of the wrist. On more careful inspection and on examination certain essential differences were noted. The radial styloid instead of being on a level with or proximal to the level of the ulnar styloid was considerably distal and in fact was distal to the normal level as compared with the left wrist. The hand instead of presenting radial deviation was in ulnar deviation. The lower fragment of the radius was displaced backwards as in a Colles's fracture and

Pennhallow Dunlap—P. (senior Clinical Orthopedics, Georgetown Univ. School of Medicine. For record and address of author see "This Week Issue" June 536.

crepitus and abnormal mobility were present. Circulation of the hand and fingers was good and there was no apparent nerve involvement.

An x-ray which was taken at that time showed a fracture line extending through the lower end of the radius with the lower fragment displaced back-

FIG 1 Showing displacement downward of the radial styloid and impaction of the mesial border. Backward displacement of the lower fragment is also shown.

wards. The lower fragment of the radius, however, instead of being impacted on the outer surface was pulled distally and separated, thus causing the radial styloid to be distal to its normal level. On the mesial edge there was impaction. As a result of this impaction on the mesial border together with

the separation of the fragment on the outer border, the hand and wrist were in a position of ulnar deviation (Fig 1).

Under gas anesthesia the fracture was reduced, the procedure in general being the same as for a Colles's fracture. There was one essential difference, however, since the fracture, after reduction,

FIG 2 Fracture after reduction showing complete anatomical reposition of the fragments.

was immobilized in a plaster cast with the hand in palmar flexion and in radial deviation.

Following the reduction another x-ray was taken which showed good reduction of the fracture and with the fragments in good position (Fig 2).

Convalescence was uneventful and there was a complete restoration of function.

A PROPOSAL FOR A CLINICO-PATHOLOGICAL CONFERENCE*

BY RAYMOND H. GOODALE, M.D.†

THE program of a hospital staff meeting should include something more than the routine reports of deaths. Attendance may be stimulated if some program is outlined from which staff members derive some benefit. To this end we have developed a modified clinico-pathological conference for a part of the program.

In the Massachusetts General Hospital clinico-pathological conference a staff member reviews a case and discusses the differential diagnosis. Usually he is not aware of the autopsy findings which are presented after he gives his clinical diagnosis. In hospitals which are not associated with medical schools, it is difficult to find staff members who are willing to lead a clinico-pathological conference in this manner. In the

Worcester City Hospital all of the current service men learn the autopsy findings of a case before the next staff meeting.

In order to teach the staff to correlate clinical and autopsy findings the author has adopted the following plan which has been successful. A committee reviews the deaths and selects four cases for discussion. Usually these are the autopsied cases. One or two of these are selected for detailed correlation of clinical and autopsy findings. At the staff meeting the staff member or interne concerned presents the pertinent clinical and laboratory data, and gives the diagnosis as it was made before the autopsy. The pathologist then gives each member a mimeographed copy of the correlated clinical and autopsy findings. He then reads the correlated data and adds comments. Next the illustrative gross organs are shown, and any microscopic material is demonstrated.

Following is an example showing the set-up used.

*From the Pathology Department, Worcester City Hospital, Worcester, Mass.

†Goodale, Raymond H.—Pathologist, City Hospital, Worcester. For record and address of author see This Week's Issue, page 596.

WORCESTER CITY HOSPITAL MEDICAL STAFF MEETING

Myelogenous Leukemia

Case of R. B., male aged fifty-six. Hosp No 233504 A145-35

Temp 99 to 102.5 Pulse 100 to 135 Resp *8

Height = 67 inches Weight = 175 lbs Blood pressure 100/60

AUTOPSY FINDINGS

CLINICAL FINDINGS

Mouth

Gums swollen and red ulcerated only at place where teeth were extracted

Gums swollen and red ulcerated only at place where teeth were extracted

Pericardial cavity

40 cc. of bloody fluid fibrinous pericarditis

Heart sounds distant.

Heart

Weight 530 Gm (normal 800 to 360 Gm)
The muscle is pale and flabby

No murmurs or enlargement. Heart sounds distant auricular flutter and fibrillation

Pleural cavities

100 cc of straw-colored fluid in each cavity

Slight dullness at both bases

Lungs

Frothy bloody fluid in both lower lobes. No pneumonia

Slight dullness with crepitant and subcrepitant rales at bases

Spleen

Weight 680 Gm (normal 150 to 200 Gm)
Fairly soft infarcts

Palpable one finger below costal margin no tenderness

Liver

Weight 2550 Gm (normal about 1500 Gm)
Smooth and firm

Not palpable

Kidneys

Weight 680 Gm (normal 270 to 360 Gm)
Soft, pale, symmetrically enlarged petechial hemorrhage in cortices and pyramids orange gravel like material in calyces

Trace of albumen many hyaline casts

Bone marrow

Megakaryocytes diminished Filled with myelocytes and myeloblasts crowding out erythroblastic tissue.

Blood smear—platelets decreased 81 per cent myelocytes 3 per cent myeloblasts Red count 1960 000 White count 120 000 to 48 000 Peroxidase stain 87 per cent granulocytic series 13 per cent lymphocytic series

Incidental findings

Small right hydrocele. Moderate arteriosclerosis of aorta

Since the introduction of this system of correlation a year ago we have noted that the internes are stimulated to have the records more thoroughly prepared. Everyone who at

tends the meetings including the pathologist, is learning the art of correlating the findings at the bedside with the autopsy material.

PREGNANCY IN BICORNATE UTERUS

A Case Report

BY M. W. PEARSON, M.D.,* AND HARLAN W. ANGLER, M.D.*

IN November 1933 a young woman Mrs. S. came to my office with the following history and symptoms:

She had skipped two menstrual periods and believed that she was pregnant. For the past two

or three days she had experienced some pain and discomfort in the pelvis with a bloody vaginal discharge.

She was a healthy well-developed woman twenty-one years of age no previous pregnancies. On pelvic examination the uterus was found enlarged to about the usual size for three months gestation in good position with a somewhat elongated cervix

*Pearson, M. W.—Chief of Staff, Mary Lade Hospital, Worcester, Mass.
*Angler, Harlan W.—Visiting Surgeon, Mary Lade Hospital, Worcester, Mass.
For records and addresses of authors see "This Week's Issue," page 196.

and no dilatation of the os After rest in bed for two or three days the pains and vaginal discharge subsided

Once or twice during the winter she had a recurrence of the same symptoms which subsided as before after rest in bed.

She lives in a neighboring town and it was only by telephone that I was in communication with her until April, 1934, when she had a more severe attack and came to the Hospital by my advice for observation In bed in the hospital no more pain or flowing occurred. The fundus of the uterus was then at about the level of the umbilicus, the cervix was still unusually long with no dilatation of the os At this time no fetal movements were made out and no fetal heart sounds heard.

We could arrive at no entirely satisfactory explanation for her history and symptoms thus far, but she was comfortable and there seemed no indication for any active interference, so she was allowed to go home

There were no further developments until June 13 about the time of her expected labor, nine months from her last regular menstrual period At this time there was recurrence of pain so she came to the hospital It was then evident that there had been no further enlargement of the abdomen since the last examination in April, and x-ray showed the outline of a fetal skeleton at about five months, in the left position, head presentation The pains soon subsided and the patient was again sent home to await developments The best we could do for a diagnosis at that time was probable fibroid with pregnancy

There was no further enlargement during the summer and she remained in the best of health, but became tired of carrying her unsightly abdominal tumor and desired to have it removed if possible Accordingly abdominal section was decided upon which was performed October 9, 1934 by Dr Harlan W Angier of Ware

Following is Dr Angier's account of the operation

A low, left paramedial incision was made On opening the peritoneum, a firm, grayish yellow mass

was exposed This was about the consistency of a fibroid, and nothing was felt which might identify it as a fetus The omentum and transverse colon were attached on the anterior surface, the cecum was adherent to the right posterior surface over an area about five centimeters in diameter, the jejunum was attached posteriorly and drawn very tight so that the impression, on passing the hand behind, was of a broad band running to the duodenum, the bladder was distorted by adhesions to the lower aspect

The omentum, intestines and bladder were separated with difficulty but little bleeding The left tube, round ligament and a short distance down the broad ligament were cut The mass was then clamped off below and removed A double layer of sutures closed the opening in the side of the uterus just above the internal os The remaining uterine tissue was about the size and shape of a normal uterus The wound was closed in layers

Examination of the mass showed a contracted, dehydrated, and degenerated uterine wall varying in thickness from 0.3 cm to 1 cm, the thickest portion being at the placenta which was 1 cm in thickness and attached through its entirety

The fetus, a male, was dehydrated and quite mummified There was no sign of decomposition Its length was 28 cm Anteroposterior diameter of the head was 9 cm All parts in apparent proportion and no evidence of deformities

Convalescence from the operation was without complications of any kind She was discharged from the Hospital on the twelfth day entirely well, and still very desirous of having a living child if possible

She menstruated normally November 10, one month from the operation, and again in December and January but not after and it became evident that she was again pregnant Gestation proceeded this time in an entirely normal manner up to full term and she was delivered October 13, 1935 of a perfectly developed 9 lb boy

The labor was without serious complications of average duration and severity for the occiput right posterior position

NO INFERIORITY FOUND IN BRAINS OF WOMEN

By The Associated Press

MOSCOW, March 10 — V P Osipoff, director of the Bekteroff Institute for the study of brains, reported tonight that there is no scientific basis for the theory that women's brains are inferior structurally to men's

The report was based on a study of 500 human brains carried on by the institute over several years

The investigations proved it is impossible to determine from its structure whether a brain belongs to a man or woman, Dr Osipoff said

He denounced the theory disproved by the study as a 'convenient argument used in some countries

to enable the strong to exploit the weak"—*New York Times*, March 11

DEALERS IN ALCOHOLIC CANDY AND PATENT MEDICINE FIND OPPOSITION IN FEDERAL LAW

Sale of alcoholic candies, which flared up in a short-lived revival following repeal, has been punished in two more Federal jurisdictions, according to the Food and Drug Administration report.

Several manufacturers and shippers of patent medicines have also been fined for having shipped products under labels carrying false statements of effectiveness, and false and fraudulent curative claims for the treatment of the conditions named.—*U S Department of Agriculture*

CASE 22121

PRESENTATION OF CASE

First Admission A thirty-four year old white American ice peddler was admitted complaining of painful swelling of the left hand.

Eleven weeks before entry he developed vesicular eruption on his fingers accompanied by itching. Despite the application of several salves the lesions persisted and spread over the hands. Finally after the institution of intra-venous therapy by a physician the eruption in the right hand improved somewhat. Two weeks before coming to the hospital there was an exacerbation of the eruption and many small vesicles became filled with pus. Four days later there appeared red streaks extending up the left forearm. The left hand became painful, red, and swollen. A few days later the patient had malaise, chilly sensations, and some tenderness in the left axilla. The entire arm became quite painful.

Physical examination showed a well developed and nourished young man. On the skin of both hands, wrists, fingers, and interdigital spaces there were scaly erythematous patches with minute vesicles and pustules. The left hand was more extensively involved and the forearm was slightly swollen, indurated, tender, and reddened to the elbow. The left epitrochlear and axillary nodes were enlarged, soft, and tender. The heart and lungs were negative. The blood pressure was 120/70. A moist scaly eruption was present between the toes.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red cell count of 4,370,000 with a hemoglobin of 80 per cent. The white cell count was 11,000, 67 per cent polymorphonuclears. A Hinton test was negative.

The patient was treated with hot medicated soaks with subsequent gradual improvement. An area of tender induration appeared on the medial aspect of the left epitrochlear region but this subsided shortly afterward. He was discharged on the eighteenth day. His temperature had never risen above 99° throughout the hospital stay.

Second Admission, five days later

On the day after discharge the patient again developed a tender reddened, hard swelling in his left forearm. On the following day he complained of pain and tenderness in the muscles of his calves. Walking was so painful that he went to bed. The next day he had a rather severe headache and some chilly sensations. The pain in the leg muscles now extended to his hips. On the day before entry he complained of vague pain in all extremities and his back. A physician was called who found the patient's temperature to be 101°. Later he became nauseated and complained of a sensation of great weight in his chest.

Physical examination showed the patient to be slightly lethargic. The vesicular rash previously described was present on his hands and feet and there was slight edema of the hands. The skin of the left forearm was mottled, red, and there were several blotchy areas on the upper arm. The eyelids were edematous. The throat was slightly injected. There was tenderness elicited in all muscles of the back, extremities, and neck. Maximal tenderness was thought to be present along the nerve trunks and there was questionable thickening of the left ulnar nerve. The neck was slightly stiffened and motion was painful. A bilateral Kernig sign was elicited. The biceps jerks were present and equal. Knee jerks were sluggish and the ankle jerks were absent.

The temperature was 103° the pulse 100. The respirations were 24.

Examination of the urine showed a slight trace of albumin but was otherwise negative. The blood showed a white cell count of 23,000, 80 per cent polymorphonuclears, 6 lymphocytes, 3 monocytes, 9 myelocytes and 2 eosinophils. The stools were negative. A lumbar puncture showed an initial pressure of 90. There were 5 lymphocytes per cubic millimeter. An ammonium sulphate test showed a questionably positive reaction. The total protein was 52 milligrams per cent. The spinal fluid sugar was 73 milligrams per cent. A Wassermann test was negative. Blood cultures were repeatedly negative. Agglutination reactions for the typhoid-dysentery group were negative. A muscle biopsy was negative for trichiniasis and vasculor disease. The phenolsulphonphthalein excretion was 95 per cent in two hours. The non-protein nitrogen of the blood was 29. The chlorides were equivalent to 95 cubic centimeters N/10 sodium chloride. The serum protein was 5.7. An electrocardiogram was negative.

X-ray examination of the chest was negative.

The patient gradually improved generally and the temperature with daily oscillations, slowly returned to normal at the end of a week. He continued to complain of pain in the left arm where tenderness was found over the ulnar

nerve with hypesthesia over its cutaneous distribution. A week later the patient had no complaints but had occasional rises of temperature to 102°. The white blood cell count remained elevated between 15,000 and 20,000. Shortly afterward he developed pain and tenderness in the left arm, leg, and side of the abdomen. On the following day there was a flare-up of the skin eruptions over both arms. Thereafter he improved and complained only of some vague joint pain. Frequent exacerbations of the generalized aches and fever were usually associated with ingravescence of the skin eruption. At the end of five weeks the patient developed tender subcutaneous nodules about two millimeters in diameter on the calves of his legs. These were transient. Eleven days later the patient requested leave to go home, and he was discharged although there was no evidence of any improvement.

Final Admission, two weeks later

Shortly after discharge the patient had stabbing pain in the left arm and right leg. The distress was sufficiently severe to require morphin for relief. He had several chills and his temperature remained fairly constantly elevated.

Physical examination showed an emaciated, gaunt, drowsy man moaning with constant pain. There was marked tenderness over all the extremities and slight tenderness of the abdomen and costovertebral angles. There was moderate brawny edema of the left hand and both feet and ankles. The mucous membranes were dry. The heart and lungs were negative. There was no evidence of any active skin lesion. The previously described skin nodules had disappeared.

The temperature was 102°, the pulse 110. The respirations were 24.

Examination of the blood showed a white cell count of 33,000, 87 per cent polymorphonuclears, 11 lymphocytes, 1 mononuclear, and 1 eosinophil. The platelets were normal in appearance. The stools were negative. The blood cholesterol was 137 milligrams per cent. The uric acid was 2.03. Again repeated blood cultures showed no growth.

A flat x-ray film of the abdomen showed a few areas of calcification above the crest of the ilium which were believed to be calcified glands. The left lobe of the liver appeared to be slightly enlarged. The chest was negative. The extremities showed some fleck-like atrophy in the region of both wrists and bones of the feet.

A week after admission the patient improved somewhat although his temperature remained slightly elevated and the white blood count remained in the vicinity of 23,000. Four days later the patient had severe right upper quadrant pain which was aggravated by inspiration. There appeared dullness, râles and bronchial breathing at the right base. The blood pressure was 150/100 and a friction rub was heard

over the precordium. The temperature was 101°. X-ray examination showed slight enlargement of the heart and cloudy dullness in both lung fields, less at the periphery and in the apices. He was considered to be moribund, but four days later had improved markedly although he complained of some substernal oppression. Dullness was now found in the left lower chest in addition to persistent signs on the right. The respirations were 42 and a friction rub was still heard over the precordium. On the twenty-third day his face became quite cyanotic and the neck veins were markedly distended. The respirations were characterized by expiratory grunting. The chest signs were unchanged. Another x-ray showed change in the previous areas of dullness which were now practically confined to the upper lung fields. A well defined rounded area of density was present in the left upper lung and there was some fluid in the left pleural cavity. The heart and upper mediastinal shadows were slightly increased in size. A week later the left arm became blue, cold and edematous. A feeble radial pulse was felt on this side. The left external jugular vein was felt to be prominent, firm, and cord-like. There was marked pitting edema of the ankles. The heart sounds were weak. The temperature was 99°, the pulse 120. Three days later purpuric spots appeared in the skin of the chest and the arms. The left arm became somewhat warmer and there was diminution of its swelling. Corneal ulcers then appeared in both eyes and he began to sink rapidly. He died on the thirty-sixth hospital day, three months after his first entry.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM D SMITH. I would like to know more about this man's occupation. I would like to know if he drove a horse, if he took care of the horse, or if the horse had a cold.

Eleven weeks before entry he developed a vesicular eruption on his fingers accompanied by itching. He might have had a dermatitis. He might have had a fungus infection. At least he had it for eleven weeks before he came into the hospital.

I do not believe the eruption improved on account of the intravenous therapy.

Of course he might have had a skin lesion and it might have become secondarily infected but when it says "many small vesicles became filled with pus" it makes one think that they were pustules from the beginning rather than lesions becoming infected from some extraneous source.

He had a lymphangitis, also a systemic reaction to his infection, whatever it was, and probably glandular enlargement in the axilla.

"On the skin of both hands, wrists, fingers, and interdigital spaces there were scaly ery-

thematous patches with minute vesicles and pustules." I am guessing that the skin lesions and the pustules were part of the disease.

He apparently had athlete's foot. I have heard Dr. Swartz say that while this type of fungus on the foot may cause a lymphangitis it does not ordinarily cause a systemic infection that is a fungus septicemia. It still leaves it open as to whether this eruption on the hand was fungus or not.

Dr. Oliver does the fungus eruption cause pustules ordinarily?

DR. E. LAWRENCE OLIVER. I think when there are pustules it is probably secondary in infection and staphylococcus. Vesicles as well as pustules make culture media.

DR. SMITH. I cannot draw any conclusions from the blood examination. We cannot say that he had a leukocytosis, although the white count is a bit more than ten thousand.

"An area of tender induration appeared on the medial aspect of the left epitrochlear region but this subsided shortly afterward." I cannot interpret that. Apparently it was not an epitrochlear gland but an indurated area in that region. If this were a pyogenic infection it would be extraordinary to have that amount of lymphangitis and that glandular involvement without some fever and increased white count.

The tenderness elicited in the muscles makes one think of periarteritis nodosa. The nerve tenderness and the thickening of the ulnar nerve make your mind jump to leprosy but it jumps back again very quickly.

"The neck was slightly stiffened and motion was painful." He had meningeal irritation at least, if he did not have meningitis.

The white count in the second admission is just a bit high. The few myelocytes do not particularly interest me. He did not have eosinophilia, which does not rule out periarteritis nodosa or other diseases where we would expect an eosinophilia.

The spinal fluid sugar is just a shade high and suggests that he certainly did not have a pyogenic meningitis.

The blood cultures were negative. That is interesting because if this were a pyogenic condition we would expect repeated blood cultures to show something. On the other hand, if this were a fungus infection or glanders we might have repeated cultures and quite likely not get a positive finding.

"A muscle biopsy was negative for trichiniasis and vascular disease." I suppose there again they are thinking of periarteritis nodosa.

This illness has been characterized by marked remissions and exacerbations when he seemed to be pretty well and then pretty sick.

The left hand and arm seem to bear the brunt of the local reaction whatever it may be.

I was hoping there would be a running nose so that we could discuss glanders.

The skin lesions in this exacerbation are gone and the previously described skin nodules are gone.

"Repeated blood cultures showed no growth." Again I think that makes it more doubtful if this were any of the ordinary pus-forming organisms.

"Four days later the patient had some right upper quadrant pain which was aggravated by inspiration." Was that pleurisy? Dr. King?

DR. DONALD S. KING. I think so.

DR. SMITH. I think it might be from the subsequent story.

"A friction rub was heard over the precordium." (The last case I discussed had a friction rub on paper but none at postmortem.)

We might think he had pericarditis, lung changes, and perhaps involvement of the mediastinal glands. He has pulmonary involvement certainly. What sort we do not know. My guess is that he has some venous thrombosis in his central vascular system or near it. I am still not willing to make a diagnosis of pneumonia. These changes jump from the lower lobes to the upper lobes in the most discouraging and distressing fashion.

The x-ray description of that "well defined round area of density" again makes one feel that the lung changes are very likely metastatic and not terminal pneumonia and that the lung pathology is part of the original disease whatever that may be.

At first glance I thought he had an arterial obstruction of the left arm but he has no business having edema. The arm should not be edematous if he has arterial obstruction so I do not know whether it was arterial or venous. If it was arterial the arm should be white and not edematous, instead of that it was blue, edematous and cold.

He may have a thrombosis in the jugular vein.

Of course the easiest thing to say is that he had a dermatitis, secondary infection a lymphangitis, and a septicopyemia.

Did he have glanders? With glanders we could have papules and pustules. We can have a chronic glanders that is difficult to diagnose. You may get with glanders, pneumonia and meningitis. Could these swellings be farcy buds that did not break down? In glanders you expect some to break down somewhere. Furthermore, if it was glanders we probably would have something in the story about the Strauss test and the malain test and the complement fixation test. Still I think glanders could cause this picture. Then having that we drop into the other queer things the mycoses. Of course,

more acute lesions since we have very carefully studied over fifty sections

At this point I suggest that we begin our differential diagnosis again. We are dealing with the chronic, perhaps with the healed stage of a diffuse arterial disease. It is not embolism because no source for emboli in the major arterial circuit was found and embolism of such a diffuse character would certainly have involved the spleen. In contrast to malignant hypertension the disease spares the arterioles. It differs from Buerger's thromboangitis obliterans in concentrating its effects upon the smaller arteries of the viscera rather than the larger vessels of the extremities. Syphilis must, I suppose, be mentioned though the evidence that it ever produces peripheral vascular disease is far from convincing and in this case the negative Hinton and Wassermann tests are adequate to exclude it. What have we left? A large group of vaguely defined disorders of the blood vessels and one other disease entity—periarteritis nodosa. Two attempts to make this diagnosis by biopsy were unsuccessful but that is not an uncommon experience when no subcutaneous nodules are present to guide one's scalpel. No characteristic lesions of the acute stage were demonstrated at autopsy. Periarteritis cases do, however, occasionally survive the acute stage to die considerably later of its consequences or of intercurrent disease. We have had one patient, proved to have periarteritis nodosa by biopsy at this hospital, who died at home nearly two years later. From Vienna one case has been reported where an autopsy was secured about four years after the acute stage of the disease. The vessels were characterized by healed miliary aneurysms—exactly what one would expect from the nature of the acute lesions. In several vessels from this patient, particularly in the liver and kidney, healed aneurysmal dilatations of small arteries are present, certainly suggestive of the lesions that have been described. The involvement of the brachial artery and vein and the lesions in the small intrahepatic portal radicles are not well explained by this diagnosis but I must leave that question open.

A PHYSICIAN: How do you explain the paradox of chronic lesions in the vessels and acute parenchymal degeneration?

DR MALLORY: Of course we may have missed acute lesions in the vessels, but, as I said, this seems to me unlikely. I would make the following series of assumptions. During the acute stage of his disease many vessels were narrowed and some were completely occluded. He must in general have developed an adequate collateral, however, for only in the heart did we find any evidence of old parenchymal degeneration. In the last few days of life his heart weakened, his blood pressure probably dropped and circulation in focal areas dropped below the critical level.

DR JONES: Was there any evidence of peritonitis? I ask because for about a week he had intense abdominal pain and tenderness and it seemed as if he had peritonitis.

DR MALLORY: I should think that pain might possibly have come from the liver infarcts. It is at least possible.

DR JONES: He had on two occasions sharp pains in the left arm, if I remember correctly, and we wondered again if he had a nodule. Material was sent for biopsy, but the sections did not suggest this at all?

DR MALLORY: No they did not.

The muscle showed very marked atrophy with a great deal of fibrosis. There are nearly occluded arteries between the muscle fibers. The peripheral nerves were negative and the spinal cord was negative.

A PHYSICIAN: Have the skin lesions any relation to this disease at all?

DR MALLORY: My guess is no. How would you feel about it, Dr. Oliver? At the time of autopsy the skin lesions had disappeared.

DR OLIVER: I think secondary infection might have had something to do with it. A pus infection on top of the skin affection might lead to this condition.

DR SMITH: What about this repeated lymphangitis and cellulitis of the arm? Was that irrespective of the underlying disease?

DR MALLORY: I should imagine he had a skin infection and lymphangitis probably unconnected with the underlying disease.

A PHYSICIAN: Were any of these peculiar changes found in the coronary arteries?

DR MALLORY: There were changes in the smaller ones, especially in the left auricle beneath the thrombi, where patches of absorption of muscle cells were found.

A PHYSICIAN: Did the heart's blood show no growth?

DR MALLORY: We did innumerable blood cultures at various times and they were all negative.

CASE 22122

PRESENTATION OF CASE

A sixty year old white Canadian housewife was admitted complaining of pain in the abdomen.

The patient had been perfectly well until two months before entry at which time she had an attack of "gall stone colic" from which she recovered completely in a few days. Two weeks before coming to the hospital she had another similar attack, during which she developed a persistent pain in the back between the shoulder blades. At this time a physician reported the palpation of an enlarged, tender gallbladder which emptied suddenly following pressure, with relief of her pain. About a week later she began

to have severe pain in the midabdomen, and a mass about the size of a small grapefruit was felt in this region. Enemata produced no relief. On the following day she was unable to move either leg. The reflexes in the right leg were absent and those in the left were sluggish. From a level midway between the xiphoid and umbilicus downward, pain, heat, and cold perception were absent. Thereafter there was no change in her condition although the abdominal pain was intermittent.

Physical examination showed a markedly obese elderly woman in no acute discomfort. The skin of the arms was dry and scaly and there was an early decubitus ulcer in the sacral region. The heart sounds were regular but rather distant. P_2 was greater than A_2 . The blood pressure was 120/80. Rales were audible at both lung bases. There was marked tenderness over and to the right of the third, fourth, fifth and sixth dorsal vertebrae. The abdomen was protuberant and firm, and there was tenderness with deep pressure in the left lower quadrant. No evidence of ascites was elicited. There was pitting edema of both ankles. There was complete paralysis of the lower extremities with weak knee jerks. The right ankle jerk was present, but the left was absent. No Babinski was elicited. There was diminution of touch perception from the fifth dorsal spine down. Vibratory sense was absent in the ankles as was position sense in the toes.

The temperature was 100° , the pulse 120. The respirations were 20.

Examination of the urine showed a specific gravity of 1.002 to 1.008 in several specimens. There was a large trace of albumin and the sediment contained large numbers of white blood cells and on one occasion was loaded with erythrocytes. Casual urine specimens were negative for Bence-Jones protein but a twenty-four hour specimen was positive. The blood showed a red cell count of 4,900,000, with a hemoglobin of 90 per cent. The white cell count was 17,500. 90 per cent polymorphonuclears, 4 lymphocytes, 4 eosinophils, and 2 unclassified cells. The non-protein nitrogen of the blood was 130 milligrams. An intramuscular phenolsulphonephthalein test showed less than 5 per cent excretion in 90 minutes. The serum protein was 11.4 grams per cent. A lumbar puncture between the third and fourth lumbar vertebrae gave an initial pressure of 110 and a final pressure of 0 after 8 cubic centimeters of clear, faintly yellow fluid was obtained. There were no respiratory oscillations observed and jugular pressure produced no change in the fluid pressure level. Examination of the spinal fluid showed 4 lymphocytes. The total protein was 560 milligrams per cent with a clot. Tests for globulin were positive. The sugar was 109 milligrams per cent and the Wassermann test was negative.

X-ray examination of the chest showed the

heart to be enlarged downward and to the left. The aorta showed a marked degree of tortuosity. The lungs were clear. The skull exhibited multiple punched-out areas without any thinning of the cortex. The sixth dorsal vertebra was collapsed and the seventh was also said to be involved. Surrounding the fifth to the seventh dorsal vertebrae was a soft tissue mass which exhibited no calcification. The ribs were normal but the remainder of the skeleton showed slight decalcification.

Shortly after admission the patient developed a generalized blotchy, macular, dull red eruption, most intense over the abdomen. This persisted for about a week, at which time a vesicular like eruption occurred about the lips. On several occasions crystals appeared upon the patient's forehead and face. About two weeks after entry the nonprotein nitrogen had gradually diminished to 68 milligrams and the patient had some return of sensation in her extremities. X-ray therapy was instituted over her kidneys, lips, and back. During the third week the patient gradually became drowsy, markedly nauseated, and her nonprotein nitrogen rose to 117 milligrams per cent. Thereafter she became stuporous and developed twitching of her hands. Her decubitus ulcers spread and concomitantly her temperature, which had fluctuated between 99° and 101° , rose to 104° , and she died on the thirty-third hospital day.

DIFFERENTIAL DIAGNOSIS

DR WYMAN RICHARDSON. Time is getting short and I will try to make this discussion brief. It is much easier to arrive at a diagnosis having gone over the entire course of this patient's illness. The difficulties confronting the physician earlier in the course of the disease, however, can easily be appreciated. If we consider the essential and important features, only one diagnosis appears to fit the facts. These features are as follows: First, a tumor involving the dorsal spine and also apparently involving the skull; secondly, a rather rapid failure of renal function; thirdly, the presence of Bence-Jones protein in the urine; fourthly, a serum protein of 11.4 grams per cent. Myeloma is the only disease which satisfactorily explains these findings. It is true that certain cases of widespread bone metastases from carcinoma have been reported in which there was Bence-Jones protein in the urine, but I am doubtful whether any such case showed a serum protein of 11.4 grams per cent. It is a well known fact that patients with myeloma frequently die in uremia. Apparently the cause for this is a precipitation of the abnormal protein in the renal tubules with consequent failure of renal function.

If we try to explain all the symptoms on this basis there are certain ones which leave us rather puzzled. The story of the palpation of an en-

larged gallbladder with sudden emptying following pressure leaves me feeling very skeptical. I do not explain this. I believe, however, that the pain in the back between the shoulder blades, in view of the later symptoms, was due to destruction by tumor of the dorsal vertebra. The sudden paralysis and the sacral ulcer were surely due to invasion of the spinal cord by tumor. The spinal fluid findings are characteristic of this.

Evidently then, the sixth dorsal vertebra has been destroyed by tumor involvement with encroachment upon the spinal cord. There does not appear to be by x-ray very widespread skeletal involvement, and the fact that there is no anemia is consistent with this idea. One wonders whether a critical eye could have detected plasma cells in the blood smear. I find it much easier to locate these cells after the diagnosis has been established by other means. It would have been interesting to have had some blood calcium determinations, as there is frequently a disturbance in calcium metabolism. I am not certain as to the nature of the skin eruption but would tend to associate it with uremia. The crystals which appeared on the patient's forehead and face were probably urea crystals. I assume that the patient died of renal failure and see no reason to suspect any other cause for her death.

I see I have not explained the presence of an abdominal mass. Nothing is said about this on examinations later on, and I am inclined to disregard it as probably due to some temporary stasis in the gastrointestinal tract.

We usually speak of myeloma as being multiple, but I am sure there have been cases of fairly localized tumors in this disease. We certainly are finding them much more frequently than we did a few years ago, undoubtedly because we are looking for them more carefully.

My diagnosis is, then, myeloma with secondary renal failure.

DR ALFRED KRANES: I may be able to answer some of Dr Richardson's questions. The patient was naturally admitted to the Neurological Service because of the paraplegia, and when the renal insufficiency was discovered I was asked to see her. The combination of renal insufficiency with normal blood pressure, skeletal pain, and cold block immediately suggested multiple myeloma, and I therefore looked for Bence-Jones proteinuria on a specimen voided at that time but was unable to find any. The next day, using a twenty-four hour specimen, we were able to demonstrate a moderate amount. This was an additional illustration of what we have seen in other cases of myeloma, namely inability to demonstrate Bence-Jones proteinuria in single urine specimens but finding it in twenty-four hour collections. The morning that we were unable to find any Bence-Jones protein in

the urine I looked over a smear for plasma cells and was able to demonstrate several, although as Dr Richardson suggests one felt more certain of their being plasma cells when the Bence Jones protein was discovered and the serum protein report was returned, and when finally the skull plate was seen we were positive about the plasma cells.

Calcium and phosphorus determinations were done and they were essentially those found in any case of renal insufficiency, the calcium being 9.98 and the phosphorus 6.25. A phosphatase showed 3.17 Bodansky units.

The abdominal mass described in the history we were unable to confirm.

CLINICAL DIAGNOSES

Multiple myeloma
Uremia

DR WYMAN RICHARDSON'S DIAGNOSES

Multiple myeloma.
Myeloma kidney

ANATOMIC DIAGNOSES

Multiple myeloma with destruction of the sixth dorsal vertebra and with compression of the spinal cord
Hydronephrosis
Myeloma kidneys
Decubitus
Perisplenitis, chronic

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY: As Dr Richardson pointed out, the diagnosis in this case once all the facts were known admitted of no possible doubt. The crux of the matter always rests in thinking of myeloma before the Bence Jones protein in the urine and the hyperproteinemia have been discovered. Dr Kranes deserves the credit for that in this case.

I take exception to only one of Dr Richardson's predictions. The spinal cord in these cases, though often showing evidence of injury, is rarely invaded by the tumor. Occasionally an epidural tumor mass may press upon it, but more often the injury is from pressure secondary to destruction of the vertebrae and angulation of the spinal column. That was the case with this patient, who showed complete destruction of the sixth dorsal vertebra with marked angulation at that point. We were limited in our autopsy to an incision in the back, but after removal of a portion of the spinal column it was possible to explore the abdominal cavity from behind. There was no tumor and no abnormality of the gallbladder that could be discovered by palpation. The kidneys were removed and showed the characteristic changes found in cases of myeloma. The tubules were

universally dilated and a considerable proportion of the collecting tubules and Henle's groups contained the dense hyaline casts which are characteristically found. One point which often serves to differentiate these casts and those found in ordinary types of nephritis is that they appear to act like mildly irritant foreign bodies provoking a cellular reaction in which monocytes predominate and foreign body giant cells are occasionally seen.

This laboratory has always had a particular interest in multiple myeloma because the first adequate description of the histology of the tumor was published by Dr. Wright from a case which died in this hospital in 1898. The earliest report of the disease was probably that of Beece Jones in 1848, but a clear picture of the gross

pathology was first published in 1873 by J. von Kussak, who gave it the name of multiple myeloma. To Dr. Wright belongs the credit for recognizing the characteristic cell as a plasma cell. The introduction of x-rays began to make the tumor readily recognizable when the cases were of the classical type with multiple small tumor nodules throughout the flat bones. In recent years we have learned that there are many clinical types. The disease can affect a single bone or can produce a diffuse leukemic involvement of all the hematopoietic marrow with absolutely no x-ray changes. It can, moreover, appear in an extra-osseous form and primary plasmocytomas of the nasal pharynx are undoubtedly another manifestation of the same process.

MORE ABOUT POLIO VACCINES

IN our issue of October third, 1935, we cautioned against the too hasty trial of vaccines advocated for the prevention of anterior poliomyelitis. It was our conviction that vaccines composed of killed virus could have little or no immunizing value. At that time, while we had very grave doubts as to the harmlessness of vaccines made from "attenuated" virus, we did not express our fears because we lacked proof of the effect of such living vaccines upon susceptible children. We privately believed that the tests to which these vaccines had been subjected fell far short of proving that they could be safely used for the immunization of human beings. To test these agents on urban adults or even on children of eight years or more could furnish no criterion for their action in children in the more susceptible age groups.

We knew that the use of small amounts of formalin, of sodium ricinoleate or other antiseptics can attenuate viruses only by diluting them. If the concentration of the added germicide is sufficient to kill the virus, the vaccine

is impotent, if lower concentrations are employed some of the virus will remain alive.

The first effect was the one sought by Brodie, the latter by Kolmer, who believed that living virus was necessary for the production of active immunity.

A careful reading of the publications of these two authors gives the impression that Brodie was confident that in his vaccine the virus was dead, while Kolmer believed that, although the virus in his preparation was living, by his treatment it had been robbed of its infectious power. The virus in the Brodie vaccine might or might not be dead—the virus in the Kolmer vaccine was living and capable of producing infection in monkeys. The fact that the injection of this viable virus into Kolmer, his two sons and his colleague was followed by no untoward results is of little significance in so far as the safety of the vaccine is concerned. The preliminary tests made by Brodie on his vaccine were, to our minds, of even less significance, since his subjects were all urban adults, who presumably were immune to anterior poliomyelitis.

So great was the demand for protection against this disease that ten thousand or more children and adults were treated with these two vaccines. Since our editorial appeared it has become increasingly evident that such vaccines may not be the innocuous agents that they have been assumed to be.

In a communication appearing in late December, written by one of the able and conservative officers of the United States Public Health Service, there were reported twelve cases of undoubted acute anterior poliomyelitis appearing in children treated with two poliomyelitis vaccines. These cases developed in a community where the disease was not prevalent, at the time of the occurrence of these cases the period elapsing between the first injection of the vaccine and the onset of symptoms would cover the incubation time of poliomyelitis infection, in every case in which the sequence was known, the level of the spinal cord first affected corresponded to the extremity in which the injection was made, the incidence of infection was greater among the vaccinated children than among unvaccinated children of the same ages and similar circumstances, and, of these twelve vaccinated children, six died—a fatality rate of fifty per cent, a rate far above that of the cases of poliomyelitis occurring last autumn throughout the country.

Furthermore, doubt has arisen as to the complete harmlessness of the Brodie vaccine.

As a result of these revelations, Park has ceased to give out the Brodie agent for human immunization and the supply of the Kolmer vaccine has been limited. Geiger, Health Commissioner of San Francisco, has recently for-

binden the use of poliomyelitis vaccines in the city and county of San Francisco

In our previous editorial we argued for extreme conservatism in accepting any agent designed for the prevention or treatment of this disease, and we emphasized the necessity for subjecting any such biological agents to rigid controls. We repeat this plea and urge physicians to be positive of the harmlessness of any such products before they use them in their practice or before giving them approval.

Polio vaccines must wait. They must be studied far more exhaustively than they have been before again being used on human beings. Medical men and public health officers also must wait, and they will be wise if they delay their adoption of these new agents until they are approved by our Federal Public Health Service.

LESS FOOD WITH MORE MEALS

More frequent and more moderate meals for the human family were suggested by Dr. Howard W. Haggard, head of the Department of Applied Physiology at Yale University, addressing delegates to the conference of the Personnel Research Foundation in New York last January. This conclusion was based on a study of medical and mental factors affecting workers in business and industry where efficiency was found to be increased when additional food, in limited quantities, was taken between breakfast and lunch and again between lunch and dinner.

The practice also proved of value in building up the health of workers who were found to be suffering from a deficiency in diet.

Even prior to Dr. Haggard's work it has unquestionably been found of benefit by many individuals to prevent the blood sugar tide from ebbing too far, apparently the omnivorous human animal fares best when a medium is struck between the habits of the carnivorous animal who eats infrequently but to repletion, and the herbivorous type which grazes practically constantly.

A change in the habits of a nation however is not made without some drastic readjustments and if Dr. Haggard's suggestions are accepted in too literal a fashion there may be some repercussion on the ever present servant problem, there will also continue to be the world's millions who are forced to ignore the blood sugar tide and draw their belts still tighter when that empty feeling overtakes them.

Perhaps, also, the true reason has been found why England, with four square meals a day, has maintained for these centuries the supremacy of

the seas. Possibly Waterloo was won, not on the cricket fields of Eton but on the roast beef of merry England.

HOUSE BILL 34

At this writing House 34 is still before the Massachusetts Senate and seems to be in line for postponement of final action because of an amendment which will probably carry it back to the House for concurrent approval unless some other action is taken. It has been the cause of stormy and acrimonious debates.

The opponents have made a significant demonstration of the purpose to block the effort to endow the State Board of Registration in Medicine with more authority to deal with the educational experience of applicants for registration.

They seem to be unappreciative of its advantages and their arguments are apparently inspired by prejudice rather than reason. It was apparent, at a recent hearing, that an aggressive minority was unable to understand the plain English construction of the bill.

The arguments submitted in opposition are singularly lacking in logic and based almost entirely on the wish to keep the door to medical practice open to the 'poor boy', completely ignoring the right of the people to have the best possible medical service. The fact that the boy without financial resources has generally been given adequate assistance to obtain an education, provided that he is otherwise well equipped, has been left out of the picture. Hence the attack has degenerated to the position of misstatements and personal abuse with all the arts of the political agitator. The Board of Registration in Medicine, the author of the bill, and the Officers and Fellows of the Massachusetts Medical Society who have worked for its passage have been criticized on the floor of the Senate Chamber in language devoid of the approved amenities of debate quite in accord with the practice sometimes reported in legal controversies.

When the bill was reported out of the House and forwarded to the Senate the following amendment was added:

"Section 3 For purposes of examination and registration osteopathic schools rated as A schools by the American Osteopathic Association shall have the same standing before the board as A schools so rated by the American Medical Association."

In the Senate several proposed amendments designed to weaken the bill have been rejected but there is probability of the following being added to the present draft:

Add at the end of section one the following:—'An applicant aggrieved by

the refusal of the board to approve a medical school under this section shall be entitled to have the reasonableness of such refusal reviewed by a justice of the superior court, whose decision shall be final."

Another amendment is pending which, if enacted, will give to the Secretary of the Board of Registration, The State Commissioner of Public Health and The State Commissioner of Education authority to determine which medical schools may be approved.

Further delay has been sought by the request to the Supreme Court for a decision as to the constitutionality of the bill. The general impression is that this bill has provoked the most animated debate of the 1936 session.

While there is a strong sentiment in favor of enactment of this bill the opposition is resourceful and will employ every legislative expedient to discourage its supporters who are still confident of success. Assuming that the arguments for special consideration of the plight of the "poor boy" are based on the opportunities existing in the substandard medical schools significant facts are presented in the preliminary report of the Registration Board examination recently held which appears on page 599 of this issue of the *Journal*, where it is shown that a majority of the applicants for registration are repeaters from medical schools which are not approved by the Council on Medical Education and Hospitals. The figures warrant careful consideration and should have influence in determining the attitude of the members of the Legislature.

Much credit is due to Senator Miles of Brockton who has carried the major burden of the proponents.

If it were possible for the women of the State to express their sentiments, there would be little doubt of the outcome. We believe that they, very generally, want for themselves and the children of the Commonwealth the blessings of scientific medicine.

The Massachusetts Medical Society

SECTION OF OBSTETRICS AND GYNECOLOGY

THE Annual Meeting of the Massachusetts Medical Society has always appealed to the membership at large because the Committee of Arrangements and the State Officers have worked unceasingly to provide a program well-balanced, and interesting to all physicians.

In furtherance of that plan, the Section devoted to Obstetrics and Gynecology will, this year, present three papers which it is felt will have a distinct appeal to the man in general practice as well as to the specialist.

One of the influential physicians in the field of obstetrics, Dr. Edward A. Schumann of Philadelphia, will read a paper on "Ante Partum Hemorrhage." This is a very timely subject because statistics in our own State show that it is one of the most common causes of maternal mortality.

Another paper will be read by Dr. F. L. Good on "Menorrhagia and Metrorrhagia of Benign Origin in Women Under Forty-Five Years, With a Plea for More Conservative Treatment." This is always an important subject, for there are divergent views as to the treatment applicable to this class of patients.

A third essay by Dr. George M. Shipton will deal with "Hospital Puerperal Sepsis." This paper will probably promote as much discussion as time will permit, for it will cover an actual series of cases and will be handled fearlessly.

The Officers of the Section earnestly urge every practitioner to plan now to attend this Section Meeting and enter into the discussion of these papers, which have been designed to bring out problems that are met in everyday practice.

The Annual Meeting is primarily for medical problems, but it will also introduce social features. Make it a three-day vacation. Ample recreation has been provided for the ladies while the doctors improve their medical knowledge.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

BENEDICT, EDWARD B. A.B., M.D. Harvard University Medical School 1923. Assistant in Surgery, Harvard University Medical School and Massachusetts General Hospital. Clinical Assistant in Bronchoscopy and Esophagoscopy, Massachusetts Eye and Ear Infirmary. His subject is Gastroscopic Observations in Neoplasia. Page 563. Address: Massachusetts General Hospital, Boston, Mass.

CARCINOMA OF THE CERVIX AND PREGNANCY

Carcinoma of the cervix and pregnancy is an uncommon combination and occurs in the ratio of one to 2000. The tumor may arise before pregnancy takes place or may become apparent only after pregnancy is well established.

The symptoms, as in all cancers of the cervix, may be slight or absent until the disease is well advanced. Early recognition of the growth must be made by examination before symptoms commence. Once the growth has reached symptom giving proportions there should occur spotting discharge, and mild hemorrhage. Pain is a late symptom and does not occur until broad ligament invasion has taken place.

On inspection the pregnant cervix, if the seat of a congenital erosion or an exposure of the endocervix due to an old laceration is vascular and edematous and suggests hyperplasia of the epithelial structures. It is usual for cervical cancer to be hard and friable but this tumor complicated by pregnancy may be soft and is often blended into the structure of the edematous cervix. In advanced cases with a cauliflower or ulcerating lesion the diagnosis is usually obvious.

When the disease is suspected the diagnosis should be confirmed by microscopic examination of a piece of tissue. The microscopic diagnosis

A series of short selected articles by members of the Section is being published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the Section.

of cervical cancer uncomplicated by pregnancy is easy but when complicated by pregnancy it may be unusually difficult. Proliferation of epithelium with down growth into the underlying connective tissue is not rare. Mitotic figures occur. The cells, however, are usually less undifferentiated and anaplastic and upon this fact the diagnosis can be accomplished.

The treatment of carcinoma of the cervix in pregnancy is not always clear but general principles can be laid down. Infection is a great hazard both in the radium and surgical treatment and careful vaginal preparation must always be carried out. In early cancer and early pregnancy, radium or total hysterectomy is the method of choice. In late cancer and early pregnancy, radium should be used. The pregnancy should be interrupted by gentle instrumentation at the time of application of radium. Miscarriage usually follows without complication.

In early cancer and a pregnancy of from three to six months, amputation of the cervix with evacuation of the uterus followed by radium treatment or a total hysterectomy should be carried out. In advanced cancer, radium followed after at least six weeks by cesarean section, depending upon the state of the fetus, is the proper procedure.

In early cancer and a pregnancy advanced to six months or beyond, treatment of the cancer with radium followed by cesarean section at the time of election is proper if a child is desired, and this method of treatment is usually satisfactory. If the child is not to be considered, a total hysterectomy may be done. If the cancer is advanced, cesarean section should be performed to save the child. This should be followed by radium treatment. The delivery of a large fetus through a radium-treated cervix is not a safe procedure and should be avoided.

The prognosis is often better than in uncomplicated cancer of the cervix,—for the tumor, because of frequent antepartum examinations, may be discovered early and either radium treatment or hysterectomy has a better than usual chance of success.

The problems of diagnosis and treatment in cases of pregnancy complicated by carcinoma of the cervix are great for the radiologist, obstetrician, and pathologist and each case is deserving of special individual consideration. No absolute rules can be laid down, but early biopsy in suspicious cases should be carried out and, on the whole, treatment with radium with due regard to the age of pregnancy is best.

AIDS TO THE COMMITTEE OF ARRANGEMENTS

BRISTOL SOUTH DISTRICT

Dr Emery C Kellogg, Swansea, Mass
Dr John C Corrigan, Fall River, Mass

A PRIZE FOR AN APPROVED ESSAY

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding a rotating internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1935-1936.

This report is to be typewritten, and when completed is to be sealed, unsigned, in a plain envelope, which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope, and sent to

The Massachusetts Medical Society,
Committee on Medical Education and Medical Diplomas,

8 Fenway, Boston, Mass

The contest this year closes May 1, 1936. Reports may be submitted at any time prior to that date.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

Postgraduate Extension Courses, scheduled this spring in the various Districts, will begin as follows

Berkshire

Thursday, March 26, at 4 30 P M, at the House of Mercy Hospital, Pittsfield. Subject: Psychobiology in General Medicine. Instructor: Kenneth J Tillotson. Melvin H. Walker, Jr, Chairman.

Bristol North

Wednesday, April 1, at 7 30 P M, at the Morton Hospital, Taunton. Subject: Acute and Chronic Nephritis. Instructor: Earle M Chapman. Arthur R. Crandell, Chairman.

Bristol South (New Bedford Section)

Friday, March 27, at 4 00 P M, at St Luke's Hospital, New Bedford. Subject: Acute and Chronic Nephritis. Instructor: James P O'Hare. Harold E Perry, Chairman.

Middlesex East*

Wednesday, April 22, at 4 00 P M, at the Melrose Hospital, Melrose. Subject: Acute Nephritis — Etiology, Diagnosis and Treatment. Nephrosis and Its Treatment. Instructor: Lyman H Hoyt. Joseph H Fay, Chairman.

Middlesex North

Friday, April 17, at 7 00 P M, at the Lowell General Hospital, Lowell. Subject: Acute and Chronic Nephritis. Instructor: James P O'Hare. Leonard C Dursthoff, Chairman.

*Inasmuch as five sessions were given in this District during the fall of 1935 there will be but five sessions this spring.

Norfolk†

Friday March 27 at 8 30 P.M., at the Norwood Hospital, Norwood Subject Immunology—Latest Developments in Immunization Smallpox, Typhoid Measles Scarlet Fever Diphtheria, Whooping Cough, and Infantile Paralysis. Instructor Gaylord W. Anderson Hugo B. C. Riemer Chairman.

Worcester (Milford Section)

Wednesday March 25 at 8 30 P.M., at the Milford Hospital Milford. Subject Gastroenterology Instructor E. Stanley Emery Joseph L. Asbkas Sub-Chairman.

†The course previously given at the Faulkner Hospital will be combined with the group at the Norwood Hospital

MISCELLANY

MASSACHUSETTS BOARD OF REGISTRATION
IN MEDICINEPRELIMINARY REPORT ON EXAMINATION HELD
MARCH 10 11 12 1936

One hundred and seventy-seven candidates presented themselves for examination on the first day. One hundred and seventy-four candidates presented themselves on the second day. Of the three candidates who withdrew on the first day all were repeaters (at least twice) one from an approved school, two from "nonapproved schools."

Fifty-six candidates took the examination for the first time 44 from approved schools, 12 from "nonapproved schools."

One hundred and eighteen candidates took the examination having failed at a previous examination of these 99 had failed at least twice, and 19 had failed at least three times.

Of the 99 repeaters 15 were from approved schools 84 were from "nonapproved schools."

Of the 19 candidates who had failed three or more times two were from "approved" schools one foreign, one in United States and 17 were from "nonapproved schools."

CONNECTICUT ITEMS

RECENT DEATHS

HURLBUTT—Augustus Moen Hurlbutt M.D., formerly a prominent surgeon of Stamford, Connecticut, died at his home March 2 1936 aged eighty-one years.

Born in Stamford, a graduate of Yale and the College of Physicians and Surgeons of New York Dr. Hurlbutt had practiced in his native town for over fifty years.

QUINTARD—Edward Quintard M.D., of New York City with a summer home in Norfolk Connecticut died at Chattanooga, Tennessee February 15, 1936. He was planning to devote his time next summer to writing a book to be called "Knollybrook Essays."

Dr. Quintard was an author of many volumes of

verse and essays as well as having been active as a medical teacher and practitioner.

MOUNTAIN—John H. Mountain M.D. City Health Officer of Middletown Connecticut, died at St. Raphael's Hospital New Haven Connecticut March 6 1936. He was a member of the State Medical Society and the American Medical Association.

MISS ABBOTT'S ELECTION

Miss Lucy B. Abbott of the William Backus Hospital Norwich Connecticut, was elected President of the New England Hospital Association at the recent meeting of this association at Boston Massachusetts.

29 000 000 VISITS TO HOMES

Dr. Howard W. Haggard Associate Professor of Applied Physiology at Yale University said the 20 000 nurses in the organizations ranks in 1935 were "probably a tenth as many as could be used to greatest advantage." The present staff in a population of 120 000 000 provides only one nurse for every 6 000 inhabitants he pointed out, and yet last year that little band made 29 000 000 visits to American homes visits of mercy and education — *New York Times* March 11.

TUBERCULOSIS ABSTRACTS

ISSUED MONTHLY BY THE NATIONAL TUBERCULOSIS
ASSOCIATION

APRIL, 1936

Those who see the steady stream of patients entering the tuberculosis sanatorium deplore the all too evident delay in making the diagnosis. About five out of each six patients in our sanatoria throughout the country are classified on admission as moderately advanced and far advanced cases of tuberculosis. One reason for delay in diagnosis is undoubtedly to be found in the lethargy of the people, coupled with the common human failing of not wishing to face unpleasant facts. Another reason is that even though the warning signals of tuberculosis have been given widespread publicity in the past, new generations are constantly appearing on the scene and older ones forget so easily. What are tuberculosis associations doing to meet this situation?

URGING EARLY DIAGNOSIS

The founders of the tuberculosis movement realized that only through broad education of the public could any progress against tuberculosis be made. The new discoveries of Koch, Nagell, Pirquet and others the promising results of Trudeau's method of treatment, the pioneering activities of Biggs, inspired hope that the disease which had resisted medical science so long could be curbed. Yet this could be accomplished only with the understanding support of the people. They must know that tuberculo-

sis is curable and preventable, that it is not a stigma, and that facilities for diagnosis and treatment must be liberally provided. Wisely the founders chose as the motive power of the new movement, public education. In the early days the exhibit and the lecture were the chief means of arousing public sentiment. Later the press printed matter and motion pictures were added. Today practically every avenue of reaching the attention of the masses is used.

Each year tuberculosis associations select a certain theme which all associations are urged to emphasize during that year. Printed matter and publicity aids are produced in advance. To make a definite impact the "release date" is set for April 1

all the educational material, care is exercised not to cause undue alarm.

The second objective sought is to encourage routine search for symptomless tuberculosis among groups of young people such as high school and college students. What is the justification for advocating this new departure?

Tuberculosis sanatorium statistics indicate that the ratio of "early cases" admitted has not increased appreciably during the past ten years. This in spite of years of earnest effort to urge people to obtain medical advice on the appearance of the early symptoms enumerated above. Many conscientious doctors constantly on the alert for tuberculosis have despaired of increasing their batting average of dis-

Type of poster design used in educational campaign

Early diagnosis was the subject of the first of these campaigns hence it was called "Early Diagnosis Campaign," a label which has persisted even though subsequent themes were on other aspects of tuberculosis control.

This year the slogan is "Fight Tuberculosis with Modern Weapons." The two objectives aimed for are (a) to remind people of the early symptoms of tuberculosis and the importance of consulting the doctor on their appearance, (b) to arouse interest in the routine search for early tuberculosis before there are symptoms and physical signs.

To achieve the former, booklets, articles and outlines for talks have been prepared calling attention to the four most common symptoms of early tuberculosis (as determined by surveys of large numbers of sanatorium patients), namely, fatigue, loss of weight, cough that hangs on and indigestion. Blood spitting, pleuritic pain and other symptoms are also mentioned. It is carefully explained that none of these symptoms is pathognomonic, but that any of them should be considered as a danger signal to be investigated by the physician. An effort is made to create appreciation for the x-ray. In

covering the disease in its incipency. The reason for that failure cannot be blamed entirely on the apathy of patients, nor on the lack of vigilance of doctors. It is to be accounted for in part by the fact that the transition from "early" or "silent" tuberculosis to the moderately advanced stage is usually a relatively swift one and only by the barest chance is the minimal case detected. So long as we are obliged to wait until symptoms betraying pulmonary damage drive the patient to our offices, we shall probably continue to despair.

Wrestling with this deplorable state of affairs, efforts have been made to devise some way of detecting tuberculosis in its silent stage among apparently healthy people. Chadwick, Rathbun, Myers and others pioneered in introducing the scheme of examining routinely, with tuberculin and the x-ray, students in colleges and high schools. This procedure, modified in various ways, has "caught on" throughout the country. The routine examination of all students brings to light early cases that might otherwise be undetected and progress to disabling disease. Lees, who examined last year all students of the University of Pennsylvania by the tuberculin

x-ray method, found 17 cases of adult type pulmonary tuberculosis of whom all were symptomless and only one was dismissed from the school. Contrast this with the usual method of "passive case finding" i.e. waiting for persons to apply to the doctor for the relief of symptoms. Lees reports that during the course of the same year 15 cases of tuberculosis had been discovered among students who came to the doctor because of one or another symptom. Twelve of the 15 were advanced cases and were obliged to leave school.

In high schools the story is substantially the same except that fewer cases of adult type tuberculosis are found. However following work of adolescent children with significant childhood type lesions leads the investigators into many homes where there is an open case. This is important, for the real threat to the youngster is probably not the calcified remains of a primary complex but daily contact with a source of infection. No wonder proponents of the routine tuberculin x-ray plan emphasize the value of locating such sources of infection. In grade schools the routine method has not been found so productive but where funds and facilities are available, it is certainly an excellent addition to our school health program.

It is with the hope that the public will accept these newer ideas for the protection of young people that demonstrations are carried on in several important colleges and schools. It is hoped that ultimately parents will depend upon the family doctor to examine their children as a matter of course with tuberculin and the x-ray when indicated. In this educational campaign tuberculosis associations look to the physician for guidance and counsel.

ROENTGENOGRAPHIC VISUALIZATION OF CEREBRAL VESSELS*

The technique of roentgenographic visualization of the cerebral vessels by injection of radio-opaque substances into the carotid artery has been only sporadically adopted since its introduction by Moniz Pinto and Lima in 1931.

The method as described by the above authors consists in exposing and ligating the common or internal carotid artery injecting colloidal thorium dioxide (thorotrast) and taking x-rays of the skull near the completion of the injection. Since this method constitutes a major surgical technique many surgeons have hesitated utilizing the procedure. Because of this objection Loman and Myerson have developed a more direct method of cerebral angiography which may be learned after a short period of practice.

Briefly this method is as follows. With the patient lying on his back and the side of the neck sterilized and novocainized a needle attached to a syringe is inserted through the skin into the common carotid artery at the level of the cricoid

cartilage. In order to make certain that the needle is well within the lumen of the vessel the needle is connected by means of a stopcock to tubing and an aneroid manometer. If the puncture is successful, the manometer needle records wide oscillations and furthermore compression of the carotid artery below the puncture site causes a quick fall in pressure followed by a rapid return to the original pressure with free oscillations when the compression is released.

If these conditions obtain, the procedure is continued as follows. An assistant either slows the arterial flow to the brain by compressing the carotid artery below the site of puncture or better still slows the cerebral venous circulation by compressing both jugular veins. While either type of compression is being continued, the operator injects as rapidly as possible 10 cc. of colloidal thorium dioxide. Rapidity of injection and adequate compression of the neck until all the x-ray plates are taken are requisites for successful visualization of the cerebral vessels. Lateral plates are taken, exposure being one-half second. The first roentgenogram taken near the completion of the injection gives a beautiful outline of the internal carotid artery and its branches. A second and third roentgenogram taken at three-second intervals give good pictures of the cerebral veins and sinuses.

Of thirty injections done by the writers neither immediate nor late ill-effects have been observed. Not only may aneurysms of the internal carotid or its branches be directly visualized by this method, but many cerebral neoplasms may be indirectly located by the presence of displacement of the cerebral arterial tree. It is probable also that other cerebral abnormalities may be determined by cerebral angiography.

CORRESPONDENCE

THE ANNUAL REGISTRATION OF PHYSICIANS

March 16 1936

Editor *New England Journal of Medicine*

The bill for Annual Registration of Physicians was referred to the Council as to the support of the Society before the Legislature.

After rather careful study I commented on various parts of the bill which seemed dangerous to the future welfare and independence of the Medical Profession. In the report of the Council Meeting in last week's *Journal* I read only an extract from an editorial in the *Journal* and this editorial favored the bill.

Some of the unfavorable features of the bill brought out in my remarks were I believe in some small part responsible for the overwhelming and almost unanimous vote by the Council not to support the bill.

For the information of the Medical Profession, I trust you will this week be able to publish the fol-

Abstract—Loman, Julius: Visualization of the cerebral vessels by direct intracarotid injection of thorium dioxide thorotrast. *Am. J. Roentgenol.* 25:113 (Feb.) 1936

lowing remarks made by me at the Council Meeting

(The bill is still before the Legislature)

ANNUAL REGISTRATION OF PHYSICIANS

According to the Editorial of December 12 1935, in *The New England Journal of Medicine*, the official organ of the Massachusetts Medical Society, "The real intent of the bill is slightly different from the obvious purpose which appears on superficial examination, The real intent of the bill is to provide accurate and adequate information, easily accessible to all, as to which physicians the state now regards as qualified to practice medicine. Annual registration is only one of the elements necessary in fulfilling this intent"

If the bill becomes a law, what its purpose is will be determined by each changing board unless some individual physician takes the matter to court. Is it not therefore wise to see how the bill affects the physician?

"Every person registered by the board as a qualified physician, who is engaged in the practice of medicine within the Commonwealth, shall annually in December, etc"

The above are the only physicians specified for annual registration. No provision is made for registering already licensed physicians who have been in Europe for a year or two or who have been ill and out of practice or who have been in practice, temporarily or otherwise, in some other state or for those who wish to enter practice at some other date than December 31.

A physician registering must record 'with the board his name, his registration number, his professional address, and such other information as the board may require'. This allows each board great latitude and if the tendency in the world toward bureaucracy and autocracy, regardless of party continues, before long physicians will be likely to find that boards at various times will require different kinds of information. "Such other information as the board may require" does not belong in the bill unless it is expected that the board will use considerable discretion in reregistering.

Furthermore applications for reregistering must be filed "on blanks furnished by the board at the request of the physician". These applications are to be remembered and filed at the busiest time of the year for physicians. If the physician is to furnish the funds, why should not the board at least be required to send out blanks?

The present laws against practicing medicine without a license are severe and it would seem, enforceable.

The need of annual lists of registered physicians seems small. Practically 5,000 of the 7,000 physicians in the state are members of the Massachusetts Medical Society and are annually published alphabetically and by cities and towns. Other organizations possibly list 1,000 more. The town and city clerks all have compulsory lists of all registered physicians in their communities. Every city and

town directory has up to date lists of physicians and the telephone directories semiannually publish more or less complete lists.

To summarize, the present laws have plenty of teeth. The vast majority of the physicians are already listed in various ways. The proposed law makes one more nuisance tax. If a law is to be enacted for annual registration and if the physicians are to raise annually \$15,000 for the use of the State, then the law should not be ambiguous, and it should be mandatory that the board register physicians already holding a Massachusetts license provided they furnish certain specific information. Disciplinary action regarding physicians is already apparently adequately provided for in existing law and no physician should feel any annual anxiety as to his registration renewal.

RICHARD DUTTON

STATE MEDICINE AND HOSPITAL SERVICE

March 10 1936

Editor, *New England Journal of Medicine*,

"City Hospital Out-Patient Department Sets Record of Nearly 500,000 Patients". Such a headline stared at the reader a few days ago in *The Boston Herald*. From further reading of the two-column article, one concludes that instead of half a million patients it meant more likely half a million consultation visits, figuring an average of five visits to a patient. I have not at hand the corresponding figures of our other large hospitals, as the Massachusetts General, the Peter Bent Brigham, the Massachusetts Memorial, and the Beth Israel Hospitals. Assuming even that the total number of consultations in all these hospitals will only equal that of the City Hospital, it would mean a round million free consultations a year in Boston alone. Taking even the lowest average of a medical fee of one dollar per consultation, it would make a sum of one million dollars in fees, of which the medical profession was deprived as an income.

Far be it from me to begrudge the unfortunates who are forced to seek free medical service. I believe 95 per cent of them belong to those, for whom each dollar given as a fee would mean so much less food, fuel, and clothing for himself and his family. They are certainly entitled to be taken care of. But the question is, who should foot the bill? Why should the medical profession alone shoulder the whole burden? Would it not be more just to arrive at an equitable distribution of this burden in form of taxation perhaps, where the medical profession would be necessarily likewise represented? Owing to the millions of free consultations, hundreds of physicians in Boston are confronted with the heavy problem of making both ends meet, and many of them are forced to give up practice and look, though mostly in vain, for anything else to eke out a living.

In view of these figures and the present deplorable situation caused by the many years of depression, I question the wisdom of our officials in the American Medical Association, as well as in our

own State Society in so bitterly opposing state or socialized medicine which at least would guarantee to physicians a minimum fee for services rendered and assure them a moderate pension when disabled or aged.

726 Washington Street
Brookline, Mass

DR RHOADS COMMENT ON "POLIO VACCINES"

The Hospital of The Rockefeller Institute
for Medical Research
66th Street and York Avenue New York

February 3 1936

Editor *New England Journal of Medicine*

I am very much interested in the editorial in *The New England Journal of Medicine* for October 3 1935 I quote from that editorial

"If we remember their laboratory experiences correctly (Harvard Infantile Paralysis Commission) it would seem that the injection of sub-infective amounts of living virulent virus repeated many times failed to produce sufficient active immunity to protect a susceptible monkey against a subsequent inoculation with a fatal dose of virus.

This is contrary to the facts since Aycock was able to immunize by sub-infective amounts and we were able to repeat this work.

C. P. RHOADS, M.D.

EDITORIAL COMMENT We welcome Dr Rhoads' comment on our editorial, "Polio Vaccines" and in order to meet his very reasonable objection and at the same time to be more explicit, we might revise the paragraph in question to read as follows: If we remember their laboratory experiences correctly (Dr Aycock and his associates of the Harvard Infantile Paralysis Commission) it would seem that while intradermal injections of active virulent virus produced immunity in the majority of monkeys to subsequent intranasal applications and intracerebral inoculations of the active virus, such intradermal injections did not consistently produce immunity in the monkeys so treated. Furthermore, although the immunizing doses of living virus were sub-infective when given intradermally they would have been rapidly infective if injected intracerebrally or even if applied intranasally. The point which we wished to make was that living virus was not a satisfactory immunizing agent.

This contention, we feel finds additional support in the results of Dr Rhoads' experiments. In his communication appearing in *Science* in 1930 there was described the use of filtrates of fresh, pooled living monkey virus and of suspensions of glycerolated material of the same strain absorbed in both cases on aluminum hydroxide. The results following the treatment of *Macaca rhesus* monkeys with the preparations were reported by Dr Rhoads as follows:

"The immunity thus induced was tested in three ways. First, glycerolated virus was repeatedly instilled into the nostrils. All the previously treated animals resisted infection although the control developed typical poliomyelitis. The second test, carried out 23 days after the first consisted of intracerebral inoculation of fresh virus. Of three animals so treated, one developed poliomyelitis as did the control, and two resisted infection. The third test was made with the blood serum of the treated monkeys. Each of the three sera was tested separately and each neutralized the virus.

It may therefore, be concluded that the virus when absorbed on aluminum hydroxide is incapable of producing poliomyelitis but still capable of inducing active immunity in *Macaca rhesus*. In a small series of animals thus immunized no symptoms of experimental poliomyelitis arose and in one only was the degree of immunity although adequate to protect against nasal instillation insufficient to protect against intracerebral injection of virus. That all three treated monkeys developed immunity is shown by the serum neutralization tests."

In a subsequent communication Dr Rhoads described his immunization experiments on monkeys with living poliomyelitis virus neutralized by convalescent human serum. We quote from the discussion:

"The results of the experiments described in the foregoing protocols indicate that a varying degree of immunity to poliomyelitis can be induced in monkeys by the intradermal and subcutaneous injection of poliomyelitis virus neutralized by mixture with human convalescent serum. That the protection conferred by such treatments is not constant, or perhaps of high degree, is evident from the fact that only one-half of the treated animals survived the direct inoculation of virus. Furthermore the serum of one of six survivors failed to neutralize a small quantity of poliomyelitis virus, although the remaining five effected complete inactivation. On the other hand six of eight animals which remained well were retested by direct virus inoculation and proved resistant."

It is interesting to compare these experiments with the refractory state resulting from the subcutaneous inoculation of active virus studied by Stewart and Rhoads. In which it was shown that four of eight treated animals were unable to resist direct intracerebral inoculation of rather weak virus strains. The foregoing experiments suggest that the production of immune bodies in certain animals may follow the injection of neutralized virus ineffective in producing disease symptoms when inoculated intracerebrally in normal monkeys.

While we regret any false impression that we may have caused by our original statement in regard to the results of the Harvard Infantile Paralysis Commission, we still firmly believe that the experimental evidence indicates that the immunity evoked by living virus has not yet been shown to be consistent or of a sufficiently high order to encourage

its use for any purpose other than for experimental study in the laboratory

DIATHERMY IN LOBAR PNEUMONIA

Editor, *New England Journal of Medicine*,
In a letter published in your *Journal* Dr Wetherbee wrote an answer to Dr King's criticism of our paper^{1, 2}, entitled "Diathermy in Lobar Pneumonia." Dr Wetherbee's correspondence contained the following paragraph

"Point 2 (dealing with the debatable question as to whether or not lung is heated by diathermy), I am referring to Dr Resnik, the physiotherapist of the group, for anything he may care to say on the subject, or on any other subject in connection with Dr King's letter" Dr Wetherbee used the correct term "debatable" To the best of my knowledge to this date we have no absolute proof either for or against this contention However, such proof was not our main concern, as may be seen from the following statement in our preliminary report "In this discussion we are concerned neither with laboratory findings nor the underlying theories as much as we are interested in the actual clinical findings The latter were gratifying" We were satisfied both from our own limited experience in this series of cases as well as from a fairly extensive and well representative literature on the subject that greater clinical improvement may be effected in the course of this disease when general medical care is coupled with the proper application of diathermy Since the publication of our report, there appeared a paper entitled "Status of Diathermy in Pneumonia" by Dr Harry Eaton Stewart

In this paper he quotes Dr Marjorie Warren of West Middlesex Hospital, London, as follows "For several winters the results were so favorable that the Directors fitted up a special diathermy ward for patients with pneumonia Shortly after it was ready last winter it was used to capacity to serve patients from a Welsh labor group who had marched on London to petition Parliament. These workers arrived in the vicinity of London in a pitiful physical state Undernourished, ragged, sleeping on the ground, they contracted pneumonia in large numbers Of these unfavorable cases over fifty were treated with a mortality of three per cent (The average mortality in England is somewhat greater than ours—about thirty five per cent.) Dr C A Robinson of the same hospital reporting on their cases as a whole gave a mortality of twelve per cent in a total of one hundred and seventy cases As these figures covered several different epidemics over considerable time they present a fair picture of results

It is now the established routine for all pneumonia cases"

"The following figures (table I) are reported from

the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company, Fairfield, Alabama, by Dr Groesbeck F Walsh

Coal and Iron Railroad Company		Re- Died		Mortality	
		cov- ered			
Treated Cases	95	83	12	12 4	per cent
Controlled "	59	47	12	20 3	" "

Thus we could go on building up statistics, sufficient quantitatively and qualitatively to support the theory that the mortality is greatly reduced by this form of treatment However, as mentioned above in our paper, we acted as impartial observers, reported facts as we found them, and stressed mainly the symptomatic relief obtained from diathermy (not at all to the exclusion of serum therapy or any other form of recognized treatment) As regards our mortality statistics we stated "The number of cases is so small that the statistics especially must be regarded with suspicion, and we feel that our results are suggestive rather than conclusive"

Dr King charged us with an act of omission He says "In regard to the physiological changes which may be expected from the use of diathermy in pneumonia, the authors have not taken into account the very careful experimental work done by Drs Binger and Christie at the Rockefeller Institute for Medical Research Their experiments on animals and on three human subjects, while perhaps not conclusive, should be given an important place in the consideration of the use of diathermy in pneumonia" I believe that Dr King answered his own question when he used the following expression "while perhaps not conclusive" With all due regard to these two investigators, we must admit that their findings were neither inconsistent with our report of benefits derived from the use of diathermy in pneumonia, nor did they disprove the theory of local heating of the consolidated lung May we quote Dr Christie's own words "Our work has been mainly confined to the physiologic effects of these currents, and we are not in a position to express any opinion as to their therapeutic value We believe that diathermy is the best method of applying heat, if penetration to the deep tissues is desired"

In their third original report, entitled "The Temperature of the Circulating Blood", Binger and Christie voiced the following opinion "This indicates that the lungs are being heated but that the blood passing through the pulmonary vessels is removing the heat at approximately the rate of production' It seems to me that this leaves very little doubt as to the fact that the lung tissue is heated locally, because heat like water would tend to flow from a higher point to a lower Furthermore, Dr King emphasizes the importance of this experimental work of Binger and Christie as being "very careful experimental work done" But Binger him

self could not have considered it absolutely faint less when he wrote the following "In the lungs of three patients suffering from lobar pneumonia no such local heating effect could be demonstrated. The discrepancy can be explained partly by the fact that in the case of dogs the anesthetic impeded the efficiency of the heat regulating mechanism, partly by the particular relation of the thermocouple to the lesion which in these patients may not have been such as to demonstrate local heat storage. The possibility of demonstrated local heating is not precluded by these observations." Thus we find Blinger himself admitting uncertainty both in the technique of those experiments and in the conclusion that might be based on their findings. For he states that *the possibility of demonstrating local heating is not precluded by these three observations*. These two admissions alone puncture the balloon which they constructed to attack the theory of local heating. The support that their work may lend to the opponents of the use of diathermy in pneumonia, becomes even weaker in the light of the analysis of Dr Stewart who was invited to assist in their study and who as he puts it, feels that he is in a position to know more than a cursory reading of the articles would afford. Therein Dr Stewart points to retractions on the part of the investigators.

Dr N. E. Titus points as follows to the injurious effects produced by the reports of Drs Blinger and Christie "In all electrical treatments technique is most important and also the apparatus used must be suitable to produce the desired reaction. Blinger and Christie neglected both of these important factors and since they did not obtain results and their conclusions had the stamp of authority diathermy as a rational aid in the treatment of pneumonia has suffered untold harm." I am in favor of a laboratory check-up on the various phases of the practice of medicine. I do not feel, however, that laboratory men have a monopoly over the power of observation. Medicine is still emerging from empiricism. Was it not Sir Oliver Lodge the great British scientist, who expressed his opinion to the effect, that laboratory investigations are only a couple of hundred years old while the human race has known of the existence of certain truths for thousands of years? Is it not in accordance with the best medical tradition that if in thousands of cases of diathermy in pneumonia improvement was observed clinically we have a right to give the patients the benefit of this therapy? And we have this right, notwithstanding the fact that a very limited effort on the part of the laboratories has not succeeded as yet to determine the factors which are responsible for the valuable aid rendered by diathermy in the general medical care in the treatment of pneumonia. As long as nobody has demonstrated that diathermy has caused any harm, and as long as its application does not exclude any other form of recognized treatment, then it seems to me that the medical profession should be encouraged rather

than discouraged, to continue with its observations in this field clinically as well as by laboratory investigations.

RECENT DEATH

MACPHEE—L. LEZ MACPHEE, M.D., of Glen Road Wellesley Massachusetts with an office in Boston died at the Hotel Commander in Cambridge his winter home, March 13 1936 after a short illness.

Dr MacPhee was born in Somerville in 1888 and received his M.D. degree from the Tufts College Medical School in 1916. He was especially interested in gastro-intestinal diseases and early in his career engaged in postgraduate medical study in Edinburgh Munich and Vienna.

Dr MacPhee is survived by his widow Mrs Berline (Grady) MacPhee two sisters and a brother.

NOTICE

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday March 26 in the Amphitheatre of the Peter Bent Brigham Hospital Dr Henry A. Christian Physician-in-Chief, Hersey Professor of the Theory and Practice of Physics in the Harvard Medical School will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12, staff rounds will be conducted by Dr Christian.

REPORTS AND NOTICES OF MEETINGS

NEW ENGLAND ROENTGEN RAY SOCIETY

The New England Roentgen Ray Society met at the Peter Bent Brigham Hospital, December 20 1935 with Dr A. S. MacMillan presiding. The program was presented by members of the staff of the Peter Bent Brigham Hospital.

Dr William Vaughan presented the first paper of the evening speaking on "Pituitary Tumors." He pointed out that while tumors of the posterior lobe of the pituitary are practically unknown adenomas of the anterior lobe are of fairly frequent occurrence. These adenomas are designated as "chromophobe"

acidophile', or "basophile", according to the staining properties of the type of the cell involved

Acidophilic adenomata produce the clinical syndrome known as "acromegaly". Dr. Vaughan discussed the case history of an acromegalic patient who developed almost total blindness over a period of three years of the disease. He was given four x-ray treatments of three hundred r units each to the pituitary region, with restoration of normal vision within three months. Dr. Vaughan cited this as typical of the excellent results obtained from radiation of acidophilic adenomata.

The history of a patient with a chromophobe adenoma who suffered severe headaches and marked visual disturbances was presented. Two series of x-ray treatments to the pituitary resulted in abolition of the headaches, and great improvement of vision. Eighty per cent of such cases respond well to radiation therapy. Failure to respond is an indication that the tumor is cystic and an indication for surgical treatment. Cystic degeneration and appearance of radioresistance may result from radiation therapy.

The "Clinical Features of Pituitary Adenomas" were discussed by Dr. Max Schnitker. The chromophobe adenomas are twice as common as all other pituitary tumors combined. They are nonsecretory and give no systemic symptoms until they become so large as to cause atrophy of other pituitary tissue, and secondary hypopituitarism with symptoms similar to those of Froehlich's syndrome. If the adenoma occurs in a child, pituitary dwarfism results. X-ray examination of these patients reveals a typical "balloon" sella turcica, which has resulted from the expanding tumor. Progressive enlargement usually occurs in the midline, and involves the optic chiasm with the production of a bitemporal visual field defect, and, eventually, if untreated, in total blindness. Occasionally growth occurs laterally and the temporal lobe of the cerebrum is involved with interruption of the optic radiation and homonymous hemianopsia. Choked optic discs and elevated intracranial pressures are rarely encountered in these tumors, and do not occur unless there is invasion of the ventricles.

Hypopituitarism manifests itself in obesity, laziness, easy fatigability, fine silken hair, and a low basal metabolic rate. Headaches may be very troublesome, but usually disappear entirely if the tumor breaks through the sella turcica. Ninety per cent of these cases seek medical advice because of slowly progressing visual defects.

Acidophilic adenoma, or diffuse increase in the number of acidophilic cells in the pituitary, results in gigantism, if occurring in the prepubertic period, and in acromegaly if occurring after puberty when the epiphyses are closed. These patients show acromegalic features, overgrowth of hair, profuse perspiration, elevation of basal metabolic rate, glycosuria, polydipsia and polyuria. Females show irregularities of menses, and males may become impotent. The sella turcica is dilated in approximately ninety per cent of the cases. Headaches are a

more troublesome feature in this group than in the chromophobe type of tumor, although visual disturbances are not so commonly encountered.

Determination of visual field changes are an important method of following progression of pituitary tumors, and of determining the efficacy of radiation therapy.

All chromophobe adenomata should be given a trial series of x-ray treatments before surgical measures are resorted to. The most widely used surgical approach to the pituitary is the transfrontal route, and well handled cases show a mortality rate of only five per cent.

Studies of the response of hypopituitary patients to hormonal medication have been ambiguous. Although the basal metabolic rate is low in such cases, there is no elevation produced by administration of desiccated thyroid in massive doses. One case with extreme lassitude was treated with injections of "Antuitrin S", without results. Subsequent administration of "Antuitrin G", however, resulted in marked subjective improvement.

Dr. Merrill C. Sosman spoke on "Pituitary Basophilism". Basophilic adenomata are very rare, and produce very striking signs and symptoms, because of their great secretory activity. Such tumors usually occur between the ages of fifteen and twenty-one years, and are more frequently found in females than in males. In a series of sixteen cases the average duration of life from onset was five years. Such patients usually show a marked adiposity of trunk and face, which spares the limbs, there is great overgrowth of hair, and excessive pigmentation of the skin. Amenorrhea develops, a low basal metabolic rate is produced, hypertension is characteristic, and there is acrocyanosis, striae distensae, hyperglycemia, and polycythemia. X-ray shows diminished density of the bones similar to that observed in hyperparathyroidism. Most of such patients die with carbuncles, or skin infections. Dr. Sosman reported two cases which showed very striking regression of symptoms, and clinical improvement from radiation therapy.

Dr. Joseph C. Aub discussed "The Clinical and Metabolic Changes Occurring in Pituitary Tumors." He pointed out that such tumors seem to produce systemic symptoms by stimulating the other glands of the body to hyperactivity. The rôle of the pituitary in carbohydrate metabolism, however, is antagonistic to that of the pancreas. Experimental removal of the pituitary results in marked increase in ability to metabolize carbohydrates, and enhances the efficacy of insulin. Ablation of both pituitary and pancreas results in mild hyperglycemia without acidosis, but restoration of the pituitary to these animals causes severe diabetes, and death from acidosis.

Studies of the calcium metabolism were made in one of the cases of basophilism reported by Dr. Sosman. During the active stage of the disease the bones showed marked decalcification, and although the blood calcium levels were normal, the calcium

output was five times that of a normal individual of the same age and weight. Following treatment and clinical improvement the calcium output dropped until at present it is but fifty per cent of the normal value. The excretion of phosphate was practically unchanged either in the active disease or following treatment.

The basal metabolic rate of this patient, which had been low before treatment, is now within normal limits. The sugar tolerance curve before treatment was of diabetic type, but after therapy carbohydrate intake causes elevation to no more than eighty milligrams per cent an abnormally small rise.

Dr W N Myhre spoke on "Teleoroentgen Treatment of Leukemia." The average life span of an individual with untreated chronic myelogenous leukemia is between one and a half and two and a half years, and spontaneous remissions are rare occurring in only seven per cent of cases. With radiation therapy life expectancy is increased thirty per cent, and remissions are induced in fifty per cent of the cases. Methods of radiation therapy have included the local radiation of the spleen, long bones and chest, and autotransfusion with irradiated blood. Such methods have given similar results. In the past twenty months forty-seven cases of chronic myelogenous leukemia have been treated with the "spray" or teleoroentgen method at the Brigham Hospital. Small doses of radiation are given to the anterior and posterior surfaces of the whole body only the head being shielded. The drop in white count seems to be directly proportional to the area of body surface so treated. Treatments are continued daily until the white count has been lowered to between ten and twenty thousand. The drop continues after cessation of treatment until the levels are seven to eight thousand. Coincident with the drop in the white count, there is an increase in the red blood cells. Radiation sickness does not occur in these cases, and remissions so induced are of greater degree and longer duration than those obtained from local treatment.

Dr William F Murphy remarked that the treatment of leukemia should be directed toward the relief of symptoms and reduction of lymphoid hyperplasia. The rise in the red count noted after spray treatment is probably due to relief of a previously overcrowded bone marrow. Between series of radiation the red count and hemoglobin should be kept well up with large doses of iron and intramuscular liver. Cases of anemia secondary to leukemia fail to show response to iron and liver except immediately after radiation.

After spray treatment the white count rises markedly (even doubles) within twenty-four or forty-eight hours. This rise is perhaps due to the production of maturation of the leukemia cells, allowing their entry to the blood stream in large numbers. This observation raises the question of

whether leukemia is a deficiency disease similar in some respects to pernicious anemia.

Dr George W Holmes stated that in his experience results obtained from the use of "spray" x ray during the past five years had not been so satisfactory as those reported from the Brigham Hospital. Radiation sickness occurs after any form of x ray therapy if the dosage employed is large enough. It may be prevented by using small divided dosages over a prolonged period of time.

NEW ENGLAND HEART ASSOCIATION

The New England Heart Association met January 6 1938 at the Peter Bent Brigham Hospital, Dr Samuel A. Levine presiding. The first paper of the evening was presented by Dr J G Gibson, M.D., on the subject A Method of Determining the Blood Volume. A modification of the dye method of determining the plasma volume developed by Gragerson, Gibson and Stead (Am. J. Physiol. 113 [Sept.] 1935) was described.

Three sources of error exist in the Keith Rowen tree technique (1) due to colorimetry of turbid solutions (plasma) (2) due to hemolysis and (3) due to variability of time required for complete mixing of injected dye, which is determined by total volume and velocity rate of the blood occurs normally in seven minutes and is prolonged in cardiac failure.

These errors are eliminated by (1) the use of the spectrophotometer (2) the use of the blue dye T 1824 (Evans) having maximum light absorption at the wave length of least absorption of hemoglobin and (3) by determining the mixing time and disappearance rate of the dye and thus the theoretical dilution value at which all the dye is mixed with all the blood before any dye has disappeared or any blood has been withdrawn.

The technique permits frequent repeated determinations since errors due to residual dye from previous injections are canceled out by the spectrophotometer.

T 1824 is nontoxic, does not pass the "blood brain barrier" and hence gives a true value for total plasma. Plasma volumes as encountered clinically may range from 2000 cc. (myxedema) to 6600 cc (congestive failure).

Dr William A. Evans, Jr., spoke on "Blood Volume Changes in Congestive Heart Failure." The blood volume in normal individuals was found subject to wide variation when expressed either in absolute quantity or in proportion to body weight. To determine the changes occurring in congestive failure two methods were used (1) Groups of individuals representing different degrees of decompensation were compared statistically and (2) observations were made on individuals during recovery from congestive failure.

Group I contained those individuals with organic heart disease but no evidence of failure and a normal venous pressure and circulation time. In Group II the subjects had dyspnea and limited activity but no signs of congestive failure. In Group

III the subjects had both signs and symptoms of failure, and a venous pressure below 150 mm. In Group IV were the severely decompensated patients with a venous pressure above 150 mm. In Groups I and II the average blood volume did not differ materially from the normal, while in Groups III and IV the average figure was increased by 20 per cent and 60 per cent, respectively.

All patients studied during recovery from decompensation exhibited a diminution in blood volume proportional to the degree of recovery. The greatest loss observed was 3780 cc. in one week. At first the loss in plasma is greater than the loss in red cells, while later the reverse occurs.

Dr Soma Weiss pointed out that this work has definitely disproved the concept of two types of congestive failure, one in which there is an increased blood volume, and the other in which there is a decreased blood volume. All cases of congestive failure are characterized by an increased volume.

Dr Michel Pijoan discussed "The Mechanism of Hypertensive Crises." Studies were made of the blood pressure and blood sugar responses following the intravenous administration of fifteen units of insulin in normal individuals, patients with essential hypertension and with Addison's disease. In twenty-five normals the blood sugar fell to a level of forty milligrams per cent without any appreciable changes in blood pressure. A sharp rise in blood pressure averaging forty millimeters of mercury, systolic, and seven millimeters of mercury, diastolic, then occurred. The blood sugar rose ten milligrams per cent, and gradually returned to the fasting level. In twenty cases of essential hypertension the initial fall in blood sugar was to an average of forty milligrams per cent, blood pressure remained constant, but then suddenly rose sharply fifty millimeters of mercury systolic, and twenty-two millimeters diastolic, at this point the blood sugar rose twenty milligrams per cent. Four patients with Addison's disease had an initial drop in blood sugar of fifteen milligrams per cent, which was sustained for two hours with a gradual rise in the next three hours with no changes in blood pressure.

In normal dogs following intravenous insulin (one unit per kilo) there occurs a drop in blood sugar from ninety milligrams per cent to twenty-five milligrams per cent without changes in blood pressure, then there is a sharp rise in both systolic and diastolic tensions (from 125 mm to 200 mm of mercury systolic and from 80 mm to 120 mm of mercury diastolic) with a rise in blood sugar of fifteen milligrams per cent. Following adrenalectomy the fall in blood sugar was sustained at a level of twenty-five milligrams per cent for one and one-half hours with a subsequent rise to normal, with no changes in blood pressures.

It was concluded that insulin hypoglycemia calls for a secretion of adrenin which is responsible for the sudden elevation in blood pressure. The response of the hypertensive to the secretion of adrenin accompanying recovery from hypoglycemia

is excessive, whereas there is no response in the patients with Addison's disease.

Dr Weiss stated that injection of adrenin in the hypertensive patient causes hyperactivity of the parasympathetic system rather than the sympathetic system, and that there is a resultant drop in blood pressure, and not an elevation and crisis. Dr Pijoan replied that if adrenin is incubated with homologous serum for several hours before injection, it will cause a rise in blood pressure.

"Hemopericardium as a Cause of Sudden Death" was discussed by Dr Marshall N. Fulton. Twenty-four instances of hemopericardium among the 3400 autopsied cases at the Peter Bent Brigham Hospital were reviewed. There were fourteen patients who died of rupture of the ventricle subsequent to coronary occlusion. In all but one of these, rupture took place within seventeen days from the onset of symptoms. There were four instances of dissecting aneurysm which bled into the pericardial sac, three of mycotic aneurysm with intrapericardial rupture, two of hemopericardium following pericardial tap, and one of so-called "spontaneous rupture" of the aorta. No cases due to trauma were encountered. The amount of blood contained within the pericardium was generally less than 500 cc. Death, in these patients, generally was sudden though not instantaneous, there usually being a period of collapse lasting two to fifteen minutes before death occurred. In one instance of rupture of the ventricle and two of dissecting aneurysm this period lasted for hours, the patients dying gradually. The diagnosis of hemopericardium may be suspected in a patient known to have one of these types of cardiac or aortic lesions who suffers collapse and dies within a brief period, usually within two to fifteen minutes.

"The Early Diagnosis of Aortic Stenosis" was the subject of Dr Samuel A. Levine's address. Some years ago the diagnosis of aortic stenosis was made much too frequently. Many basal systolic murmurs which were eventually found to be benign or which accompanied nonvalvular disease of the heart were misinterpreted as due to aortic stenosis. There then followed a period of skepticism about the significance of the systolic murmur, and it was taught that aortic stenosis was a very rare condition. In fact one of the most noted authorities on heart disease in a recent book stated that this lesion is rare. Postmortem studies, on the contrary, show that stenosis of the aortic valve is almost as frequent as of the mitral, but that in many cases the diagnosis is overlooked.

A fairly certain diagnosis of aortic stenosis can be made if one finds a loud harsh systolic murmur and systolic thrill at the base of the heart, especially in the aortic area. The finding of calcification of the valve on fluoroscopic examination is practically pathognomonic. However, the valve will be stenosed for years before either a thrill will become palpable or calcification visible. A review of sixteen cases of definite aortic stenosis seen in pri-

vate practice in which the diagnosis eventually was made but which were previously seen and not properly diagnosed has convinced Dr Lervia that this lesion must be suspected or diagnosed even in the absence of a thrill when a loud harsh systolic murmur (grade three or louder) is heard at the base of the heart. Occasionally the systolic murmur will be as loud or louder at the apex than in the aortic area. This is particularly true in the absence of hypertension, for when the latter is present and occasionally under other circumstances a loud basal systolic murmur may be present without aortic stenosis.

Dr A. W. Contratto reported on "Aortic Stenosis Syncope Angina Pectoris, and Sudden Death. The study was undertaken in an attempt to determine if there was any relationship between aortic stenosis carotid sinus irritability and syncope and sudden death or between aortic stenosis, angina pectoris and sudden death. One hundred and sixty cases of aortic stenosis were studied. Of this number one hundred were males and sixty were females. In this series fifty were autopsied cases. The average age of the patients in this series was fifty-one years. Eleven of the fifty-two cases in which the form of death was known died suddenly.

Syncope was a common complaint in twelve per cent of the cases. Marked vertigo was a prominent symptom in an additional ten per cent. No cause of the frequent occurrence of syncope in patients with aortic stenosis was determined. Fifteen patients with aortic stenosis were studied for carotid sinus irritability with negative results.

A large incidence of precordial pain was found in this series, twenty per cent having definite angina pectoris and twelve per cent having prominent precordial pain not characteristic of angina pectoris. Angina pectoris was as common in patients having aortic stenosis without aortic insufficiency as it was in those patients having aortic stenosis with some degree of aortic insufficiency. Six of the eleven cases that died suddenly in this series had angina pectoris. Also in studying the autopsy material in fifty cases, a large incidence of coronary sclerosis was found. Thus, it was felt that a large proportion of patients with aortic stenosis who die suddenly die with angina pectoris.

In "Digitalis Present in Body Fluids in Digitalized Patients" was the topic of the paper delivered by Dr Menrice A. Schnitker. It was noted that some patients complained of weakness, headache, nausea, and occasionally vomiting following salyrgan diuretics. If digitalis acting substances can be demonstrated in edema fluid, the mechanism may be that the patient is re-digitalized with a rapid elimination of fluid. Analyses were made of pleural and ascitic fluid from seven digitalized patients in which the fluid was known to have accumulated while digitalis was being taken. For controls similar fluids from four patients known to have had no digitalis were used. A precipitate obtained by treating the fluid with alcohol extracting with chloroform, reextract

ing with ether-petroleum benzine was suspended in Clark's solution. This was tested in the Strömberg frog heart preparation.

The effects recorded on a kymograph compared with standard curves of digitalis showed very suggestive evidence of digitalis bodies in the seven digitalized fluids. In none of the controls was a digitalis-like effect observed. With digitalized fluid recovery of the heart could not be obtained by washing or by atropine. These measures caused recovery with non-digitalized fluids. Chemical tests, though not specific, have shown only two positive of six tests. These observations furnished suggestive but not conclusive evidence that digitalis is present in body fluids of digitalized patients.

TRUDEAU MEDICAL SOCIETY

The annual open meeting of the Trudeau Medical Society was held in the Beth Israel Hospital on the evening of February 11. Dr Richard H. Overholt presided.

Dr Max Pinner spoke on "The Diagnostic and Prognostic Significance of Positive and Negative Sputum." Dr Pinner pointed out several exceptions to the usual rule that the finding of a positive sputum makes the diagnosis of pulmonary tuberculosis. In the first place patients may have tuberculosis with a positive sputum but there may also be another more important disease present. Secondly a positive sputum may come from tuberculous lesions in the tonsils or larynx without any pulmonary tuberculosis; although these cases are rare. Thirdly in compensation and insurance cases patients may secure positive sputum from other people and pass it off as their own. Fourthly there are about twenty-five species of acid fast organisms in sputa which are not tubercle bacilli, and these may be isolated only by culture and guinea pig inoculation. For this reason, whenever there is a discrepancy between the clinical and laboratory findings the bacilli should be carefully cultured. With these exceptions a positive sputum means active positive pulmonary tuberculosis.

Less than one per cent of active pulmonary tuberculosis patients have negative sputum when the sputum is studied by direct smear concentration methods culture or inoculation. For this reason failure to find the tubercle bacilli in the sputum practically excludes active pulmonary tuberculosis. Negative sputum, contrary to the statement of many textbooks has definite diagnostic significance and Dr Pinner showed slides of several x-rays to demonstrate this point. However in the hematogenous, nonmiliary diffuse pulmonary tuberculosis the sputum is negative. In the series which Dr Pinner presented only nine out of five hundred sputa had to be cultured or inoculated into guinea pigs to show the presence of the tubercle bacilli. In all the other cases they were found either by direct smear or by concentration methods. The most reliable criterion for a closed cavity is a negative sputum. Dr Pinner pointed out the im-

been so treated, tying together of the tendons may be done from within out. This method minimizes operative trauma. Again the stitch does not penetrate the core of the tendon at the severed surface. Core-penetrating sutures provoke more scar tissue between the tendon-ends. The scar may stretch producing a little slack which defeats complete restoration of function.

unsurmountable disability in a middle-aged pianist or harpist. We should always strive for maximum results. I use a banjo splint with a rubber-band to support the antagonizing flexor. The elastic is removed every hour for active exercise of the repaired extensors. The device is also used following the repair of extensor tendons at the knuckles.

FIGURE 1

Tendon suture. The size of the silk has been exaggerated. A Start of stitch from under surface of tendon. B Single knot and overcasting down to severed surface which is not penetrated. C Both ends of severed tendon provided with stitches ready to tie. D Shorter stitch ends tied and longer ends being tied. E Side view of tendon with stitches tied. The upper surface of the tendon is to the left.

A few years ago Koch, Mason, and Shearon pointed out the disadvantages of sutures which pierce the core of the tendon end^{3, 4}.

The film will next illustrate devices for limiting antagonizing muscles, first, in the repair of flexors of the wrist with coincident nerve repair⁵. The film will show an aluminum splint covered with felt and provided with three buckle straps which encircle the forearm, wrist and palm. (See fig 2.) The splint maintains the wrist in flexion but permits active use of the fingers. Each phalanx is exercised separately as shown previously in the film. Tension on the sutured nerves, which would inhibit their regeneration, is however prevented by the flexed splint.

With the hand in repose the thumb is somewhat flexed. The flexors are stronger than the extensors. Following repair of the extensors, unless this steady pull is relieved, the repaired tendons will be stretched and complete restoration of function will not be attained. This may not be important in a laborer but may be an

The film will show a patient to illustrate the use of the banjo splint with rubber-band support. A fish monger of eighteen had severed the extensor pollicis longus of his right hand with a fish knife a few hours before I saw him (February 14, 1935). He presented a $\frac{3}{4}$ inch transverse incised wound over the metacarpophalangeal joint which severed the long extensor of the thumb and opened the joint. Immediate tenorrhaphy was done through a $2\frac{1}{2}$ " posterolateral incision. The tendon-ends were found separated about an inch. Few interrupted 00 plain gut to fascia silk to skin, alcohol dressing, banjo splint with terminal phalanx held in hyperextension by a rubber band. February 16 active motions started. February 18 discharged from hospital. February 20 (six days after injury) film taken showing patient actively exercising the sutured tendon. March 12 discharged to Insurance Clinic. March 18 resumed former work at former pay.

Following the repair of the thumb extensors the banjo splint with rubber-band is worn for twelve or thirteen days. It is then replaced by a figure-of-eight adhesive strapping to support the proximal joint and a metal splint to support the distal joint in slight hyperextension. The metal splint is of aluminum and is removed each hour for active exercise of the sutured extensors. The strapping is changed once during the next ten days, when it is omitted. The metal splint is worn for another week or

ten days. It may be worn at night for a longer period. (See fig 3)

The film will show a patient to illustrate the use of the removable aluminum finger splint. A dentist of thirty-two on January 10 1935 severed the long extensor of his left thumb with a saw. Immediate repair by a local physician was attempted but failed. I saw the patient on January 23 found the long extensor functionless and the wound still unhealed. February 1 incision along the radial border of the thumb and first metacarpal exposed the divided tendon bridged by a scar tissue band which was adherent to the surrounding tissues. Tenorrhaphy

the strain of hemolytic streptococcus from which the donor has recovered and that with which the patient is infected should be identical. Practically, in my experience, absolute specificity is not always necessary. If the bloods are compatible, even if the strain of hemolytic streptococcus is undetermined in either individual it is intelligent practice to use the recently recovered individual as a donor for a whole blood transfusion to the patient without delaying the transfusion until it is determined that the proposed donor has been and the recipient is infected with the same strain of hemolytic streptococcus. Hemologic studies may be started at the time which may prove profitable if the transfusion fails. The donor of the second transfusion to the first patient illustrated in the film was known to have recovered from a different

FIGURE 1

Felt-covered aluminum splint used following repair of nerves and flexor tendons at wrist. A. The splint has been gently angulated to receive the flexed wrist. B. Splint in use. Although thumb and fingers can be actively moved, extension of the wrist is prevented. The splint does not fit the subject the forearm portion is too short and the hand portion too long.

closure dressing and banjo splint, as in previous case. February 3 discharged from hospital. Active exercises as in previous case. February 13 banjo splint removed. Figure-of-eight adhesive dressing applied to support proximal joint and removable metal splint to support distal joint. Distal joint to be actively exercised several times every hour. February 23 strapping removed. Use of metal splint continued till March 8. Obtained a perfect result.

The remainder of the film shows several stages in the treatment of two cases desperately ill with hemolytic streptococcus infections. Its purpose is to illustrate three principles in the treatment of such cases: 1, immune transfusion, 2, the feasibility and desirability of early active motions, 3 the preservation of tendons following the drainage of tendon sheaths and bursae. Theoretically in immune transfusion

FIGURE 2

Readily removable aluminum splint used to hold terminal phalanx in extension (to eliminate the antagonistic pull of flexor) following repair of extensors of thumb (as described in text) and avulsion of extensors in terminal phalanges.

strain than that with which the patient was infected. In the second case the strain of the hemolytic streptococcus of the recipient was undetermined. From my experience with immune transfusion the benefit derived from the donor's blood may not be solely attributable to the specificity of the strain of the hemolytic streptococcus. It would seem that the whole blood of the donor may at times contribute actively phagocytic leucocytes and an opsonin which does not demand absolute specificity of strain. There may be other factors which con-

tribute to the efficacy of such nonspecific transfusions *

The first of the two streptococcus cases illustrated in the film showed the right hand of a young physician. I saw him twelve hours after the middle finger of the right hand had been widely opened. The finger was then completely gangrenous. The white count had fallen from 20,000 to 9,000 and he was desperately ill. The finger was disarticulated, the proximal portion of the flexor sheath opened and the flaps left wide open for dakinization. Two immune transfusions were performed using as donors individuals who had recovered from hemolytic streptococcus throat infections. I am indebted to Dr Lyons, surgical resident at the Massachusetts General Hospital, for bacteriological studies in this case. The strain of hemolytic streptococcus was not the same in either of the donors or the patient. The patient's leucocytes showed practically no phagocytic activity. However, after the second transfusion the patient improved rapidly. Active motions of the thumb and remaining fingers were started ten days after the disarticulation. The film was taken nineteen days after disarticulation. Belt-knotting for finger exercise was started fourteen days after disarticulation. He resumed practice five weeks later. Subsequently a plastic will be done on the stump.

The second of the two streptococcus cases illustrated in the film shows the right hand of a butcher of fifty. He had sustained a punctured wound of the thumb two days previously. July 23, 1935, I saw him and performed an immediate drainage of the tendon sheath of the long flexor of the thumb, the radial bursa, and the wrist space. There was no evidence of involvement of the ulnar bursa. Culture showed hemolytic streptococcus. July 30 (one week later), the ulnar bursa became involved. The infection spread with such rapidity that within a few hours the little finger was gangrenous and the patient's general condition was alarming. The ulnar bursa was drained and an immune transfusion was given. The previous patient served as donor. Their bloods were compatible (Group II) but the strain of hemolytic streptococcus in the present case was unknown. However, improvement was immediate and the patient continued to make a satisfactory recovery. Active motion of the digits was started August 3 (ten days after the first operation and four days after the second operation). August 12 (thirteen days after the second operation) a film was made to show the incisions, motions, and the preservation of flexor tendons of the thumb and little finger. August 13 (the next day) the gangrenous little finger was disarticulated at the metacarpophalangeal joint and the flaps were left wide open for continued dakinization. August 31, discharged from hospital. September 7 (three weeks later) film was taken to show the condition of wounds, the degree of active motion, and the preservation of the flexor pollicis longus tendon. Subsequent progress was satisfactory.

In cases of infection of the finger sheaths and the radial and ulnar bursae the preservation of the involved tendons cannot be assured. If the mesotenon does not undergo necrosis or

if its vessels do not become thrombosed, the tendon will survive. The indications, therefore, are prompt adequate incision, and drainage in such a manner that the tendon blood-supply is not jeopardized in sheath infections. I never dislodge the tendon from its bed. I prefer to use multiple small gauze drains impregnated with boric ointment, laid lightly into the wound to hold the mouth of the wound open, *not* pushed down beside the tendon.

DISCUSSION

DR ALLEN G. RICE, Springfield, Mass. *Mr President and Gentlemen*—I think it has been eight years since we have listened to anything about the hand. It seems to me a rather important aspect of our work, especially in these days of industrial accidents.

After this very beautiful demonstration, I hate to say anything that would blur this excellent picture which Dr Harmer has left us. All I feel confident to say is that I think there is a place for splints at times. I do not think you can make any hard and fast rule that splints are to be removed forty eight hours or three days or five days later. I think it all depends on the case. It is pretty hard sometimes to judge just when the splints should be removed and when to start motion. I think perhaps the best criterion is the patient himself.

If the motion is slight, he will have very little pain. I am inclined to leave it to the patient himself, to make him start motion. If it hurts him too much, stop. Then begin again and let him move up to the point when it causes him pain.

Otherwise, I think I have very little to say, except to agree heartily with Dr Harmer's points. He spent most of his time on tendon sutures. Some of us out in the crossroads see a lot of bad hand injuries. It is surprising to see the results that can be obtained if you let them alone. The tendency sometimes is to do some sort of surgery on them.

The very tip of the finger can, I think, best be treated with a celluloid cuff that projects beyond the end of the finger. Let it fill up with blood and leave it alone. That finger will mold itself a pretty satisfactory pulp.

Another instance where the pulp has been entirely cut away, I had a little while ago a young lady who played the violin. She was slicing bread and sliced the whole pulp off the end of her left finger. That left finger of hers was rather important.

In casting around for a place that had no hair and would look pretty well, I bethought me of the toe. I took the pulp off the toe and put it on the end of the finger, and, much to my surprise, it worked pretty well. Fingers that are cut off by saws with nothing left except perhaps one little artery on the side, can yet be saved. Wrists with not only tendons gone, but both arteries, can be saved. There is a little bit of an artery that runs down the middle. That is sufficient, lots of times to preserve that hand.

I have enjoyed this paper very much.

PRESIDENT JOHNSON. Is there any further discussion?

DR JOHN HOMANS, Boston, Mass. I am not quite sure that it is germane to this discussion but it occurs to me to speak about a method of filling a considerable gap in a tendon which I have used in the case of one of the extensors of the thumb. It is perhaps a little clumsy but permits very early use. If a piece of fascia lata is taken, fairly narrow and split into two tails at either end, those two tails

*NOTE. My first immune transfusion was done in 1930. On April 14 I had operated upon a doctor desperately ill with a hemolytic streptococcus infection of his left index finger sustained by a needle prick. On June 11 I performed an appendectomy with drainage on a child. The culture proved to be a hemolytic streptococcus. Some days later the child went into collapse. I transfused the child with the doctor's blood. The immediate benefit was not less than spectacular. The strain of hemolytic streptococcus was unknown in either donor or recipient. I fully realize that this procedure was not scientific but the happy result in this case has been happily repeated in other cases since then.

can be wound around in a spiral manner one against the other so as to require very little sewing. Such an attachment can be made to each stump of the divided tendon with very few stitches and the harder the pull the tighter the lacing. So one feels very comfortable about making early use of such a union.

PRESIDENT JOHNSON Is there any further discussion? If not will you close the discussion Dr. Harmer?

DR. HARMER The title of my paper suggested the boundaries of some of the early grants of land in this country bounded on the east by the Atlantic Ocean and the west by the setting sun. I have tried to pick out just a few points to illustrate active motion or active motion with partial restriction of antagonistic tendons.

What Dr. Rice said is the same criterion which I use. If the flexor tendons are severed we will say at the wrist with nerve injury and coincident repair has been done I have the patient move the fingers in flexion up to the point of pain as Dr. Rice said

but prevent the fingers from being carried into extreme extension.

As for the practice of conservatism in hand injuries that cannot be too strongly emphasized. Hands which look desolate from crushes should have simple débridement done followed by dakinization even in the presence of fractures. Treatment of the soft parts may be more important than treatment of the bones. The fractures I think, at first should be disregarded and no primary effort made to align them. What we are more concerned with is the ultimate function of the hand rather than its appearance. Later work can be done to improve the appearance.

Dr. Homans' remark about the tendon graft is interesting. I have used fascia lata where I have had a good many tendons to repair. In short gaps I like to use tendon for the grafts rather than fascia lata although the fascia lata lace, as was said, gives you a feeling of security that it is not going to pull out.

I have been in the habit of using the palmaris longus when it was present or strips from the side of the tendo achillis or the plantaris when present.

THE ACTIVITY OF THE URINARY BLADDER AS MEASURED BY A NEW AND INEXPENSIVE CYSTOMETER*

BY DONALD MUNRO, M.D.†

IN an attempt to arrive at a better method of treating urinary bladders paralyzed as the result of spinal cord injuries it was soon demonstrated that cystometrograms were essential. A Rose cystometer¹ was tried but proved unsatisfactory for various reasons. In the first place the small graph did not show the individual contractions in sufficient detail. Secondly, the rapid fill inherent in this instrument masked the true contractile activity of the detrusor muscle and set up false levels of intravesical pressure. Finally these defects plus the limited amount of funds at my disposal made its cost prohibitive. At that time there was no other cystometric apparatus available except the experimental one devised by Denny Brown and Robertson.² I therefore adapted the tidal drainage apparatus which I had described before the New England Surgical Society in 1934³ for this purpose. I found that this provided a sufficiently accurate though crude home-made instrument. It was simple to operate and permitted the taking of observations at any desired rate of fill. Graphs made with its help were detailed enough to demonstrate minor as well as major variations in the contractile wave and it was constructed with the expenditure of about two hours of labor and \$5.00 worth of material. It was used at first in the study and treatment of abnormal bladder activity associated with spinal cord injuries. A preliminary report of these findings was made at the time the tidal drainage apparatus

was described as noted above. Since then this cystometer has been more widely used in a variety of normal and diseased conditions and in addition as a major therapeutic aid in the treatment of an increasing number of spinal cord injuries. This paper, however, is limited to a description of the cystometer and the presentation of the data derived from the study of the activity of thirty-one normal bladders. The observations were made on men, women and children and by a variety of operators.

With the antecedent tidal drainage apparatus, infection of the genito-urinary tract and the associated nursing problem of the constantly wet bed in spinal cord injuries of all types have been completely eliminated during the past two and a half years. With this additional cystometric modification and an associated graphic background of normal human urinary bladder activity the atrophic overdistended, and the hypertrophic shrunken bladders have also been eliminated. As a corollary, information is now available regarding the tonic response of the bladder muscle at the start of filling, the curve of increase of intravesical pressure with continuing distention and the frequency and type of reflex motor response initiated by a standard rate and amount of fill. By inference and because of the work of Denny Brown and Robertson,² the reflex activity of the two sphincters and the voluntary control over the external sphincter are also demonstrable. This should make obsolete any such inaccurate classification as is implied by the term "neurogenic" and lead to a more intelligent understanding of the requisite treatment in certain types of bladder disease.

*From the Neurological Service, Boston City Hospital.
†Read in abstract before a joint meeting of the Philadelphia Academy of Surgery and Boston Surgical Society at Boston, Massachusetts, February 3, 1934.

†Munro, Donald—Visiting Surgeon in Charge of Neurological Surgery, Boston City Hospital. For record and address of author see "This Week's Issue," page 625.

*The Cystometer** (Figure 1) In its essentials the cystometer consists of a large U tube with a side opening in the proximal arm. The latter is connected with the bladder by a length of tubing attached at its distal end to an in-lying catheter. To the upper end of the former, and 70 cm above this side outlet, an air-tight "Murphy dropper" is attached to a 500 cc container graduated in 25 cc amounts. Above the

FIGURE 1

dropper an adjustable compressor surrounds the connecting tube. This regulates the rate of flow from the container to the dropper and permits its estimation in terms of drops per minute. The optimum rate has proved to be about 120 drops per minute. The other distal arm of the U tube is formed by a 70 cm glass tubing of 4 mm bore marked every $\frac{1}{2}$ cm from a zero point which is set close to the level of the bladder connecting arm. Introduced into the bladder connection is an air vent which is of the same length as the manometer together with a three-way stopcock which allows fractional emptying of the bladder.

With the patient as nearly as possible horizontal, readings are taken with the apparatus hung on a stand at such a height that the zero point on the manometer is at the level of the patient's pubis. Under aseptic precautions the patient is catheterized, the bladder emptied and the catheter fixed in the urethra with the eye

just inside the internal sphincter. In males it is preferable to use a soft rubber rectal tube of appropriate size because of the terminal opening. With the catheter attached and clamped off close to the meatus the cystometer is filled to the zero point with irrigating fluid from the graduated container. After making sure that the air is all out of the system the catheter is unclamped and the test filling started by adjusting the dropper so that the flow is at the rate of 120 drops per minute. Inasmuch as the system is air-tight and the bladder and manometer contents are in hydrostatic equilibrium, changes in the intravesical pressure will be registered on the manometer as rises and falls of the column of fluid contained therein. Contraction of the bladder wall or increase in this pressure will cause a rise in manometric fluid and relaxation the opposite. Respiratory excursions are visible constantly as are sudden alterations in intra-abdominal pressure when they occur. By starting the observations with the cystometer filled and the level of fluid in the container at 0 it is easily possible to make readings of intravesical pressure on the manometer scale simultaneously with notations of the amount of fluid that has emptied from the container into the bladder. These figures are recorded in parallel columns at the time of the observation. Later, they can, if necessary, be transferred to coordinate paper in such a way as to produce a graph which has for its abscissa or horizontal arm the fluid content of the bladder, and for its ordinate or vertical arm the intravesical pressure at a corresponding moment. This apparatus is admittedly much less accurate than that of Denny-Brown and Robertson but on the other hand is considerably more accurate than the Rose cystometer. Furthermore its accuracy is well beyond the requirements of daily practicality. Although there is a positive inflow pressure, the slow rate and the additional safety valve effect as provided by the open ends of the manometer and an vent prevent significant artificial alteration of the measurements. The readings of pressure are isometric below 70 cm or in accordance with the height of the air vent. In the presence of a leak about the catheter or overflow from the manometer or an vent above 70 cm they become isotonic. When recording, each change in intravesical pressure, as evidenced by a rise or fall in the column of fluid in the manometer, is noted. The corresponding increase in bladder content as evidenced by a fall in the level of fluid in the graduated container is also listed. Care must be exercised to make the recordings in such a way as to differentiate the step rises of pressure as seen in the normal bladder and the steady rise and fall to and from a peak as seen with uncooperative patients or in completely atonic bladders.

After completing the observations detailed

*A commercial form of this cystometer has been constructed by and is obtainable from the Randall Falchney Co. Inc. 123 Heath Street, Roxbury, Massachusetts.

above, if the stopcock in the bladder connection is set at any predetermined level *above* the zero point, the full bladder may then be made to empty against positive pressure. With the stopcock at zero and no further emptying a true picture of the residual urine in the given case may be obtained by then withdrawing by siphonage (with the stopcock *below* zero) and measuring any remaining bladder contents.

Observations Measurements as outlined above have been made with this apparatus on thirty one patients who had at the time no blad-

were ten of these observations of which one is illustrated. These were made on patients who, because of associated brain tumors (4), senility (1) or low intellectual level (5), were characterized by an absence of the psychological inhibitions commonly seen in the social relationships of normal individuals. They were conscious, clean in their personal habits, completely cognizant of the need for a bedpan or urinal but their judgment in relation to such problems was conspicuous by its absence.

The graph in this type of response shows

FIGURE

der abnormalities whatsoever. Twenty four of these thirty one had never had before, nor did they have after the observation any subjective or objective vesical abnormality. Of the remaining seven three were made following presacral neurectomies for dysmenorrhea (through the courtesy of Dr Frank Pemberton), three after cervical hematomyelia with various degrees of fracture dislocation of the cervical spine and one three months after a compression fracture of the second lumbar vertebra.

In general it was possible to demonstrate three types of normal bladder activity as expressed in graphic form. The first may be considered as the true expression of the pure normal segmental reflex activity of the bladder in that the contractions were not inhibited by psychological influences. (Figure 2) There

that a fairly constant amount of stretch of the vesical wall as measured by cubic contents of the bladder produces a sudden sharp rise in intravesical pressure. Thus either ascends at once to an emptying peak or reaches there by the imposition of several increasingly stronger contraction waves one on the other. After a sufficient leakage has taken place the intravesical pressure descends again by steps to a slightly higher base than previously if the leak has been small, or to the original base level if the leak has been larger. These peaks of contraction are uniphasic with a plateau at the apices and are more or less evenly spaced. The intervals between are given over to a succession of periods of distention against a constant resistance, interrupted at intervals by waves of contraction which do not produce emptying but slightly the level of resistance to

further distention. Because of the variations due to leakage it was impossible to include these figures in the average graphs made up from the other two series. Similar graphs (not reproduced here) have been obtained in cases with proved transection of the thoracic cord. Here there was necessarily an associated anatomical severance of the bladder from the influence of higher intellectual centres although detailed studies showed normal function and anatomy of all parts of the genito-urinary tracts. These graphs also correspond within

uses. This is associated with stretching of the detrusor muscle interspersed with contraction waves only large enough to increase the resistance to further distention until at a certain critical point any given wave may suddenly build itself up to emptying levels. Instead of subsiding to the former precontraction pressure level after partial emptying, other large waves immediately follow in rapid succession. This gives the appearance of tetany on the graph and in the manometer, a condition that in all probability is actually present. In my experience

FIGURE 3

the limits of comparison of the two methods, to the observations of Denny-Brown and Robertson.

The second type of normal bladder activity is that in which inhibitions from higher levels act to prevent detrusor contractions until the tetanic level of stretch of the muscle has been reached (Figure 3). With slow filling and without mechanical obstruction of the outlet every bladder will undoubtedly sooner or later reach this level under these conditions. However, because in these observations the amount of fill of the bladder at any one test has been arbitrarily set at 400 cc or less, it has been possible to separate this group as those bladders which go into tetany within the limits of that fill. Here the intravesical pressure slowly

this type of graph has not been duplicated outside of a normal bladder and conforms as well to certain of the data obtained by Denny-Brown and Robertson. There were eight such patients. All had normal bladders, the graphs of which are represented by the one reproduced herewith (Figure 3) (Figure 5A).

The third type of normal bladder activity is that in which emptying contractions are totally inhibited until after 400 cc or more has been added to the empty bladder (Figure 4). There were eleven of these without previous bladder abnormality with an additional two in whom the graph was the same although made after pre-sacral neurectomy. These base lines duplicate those of the two other types of graph (Figure 5B) and also conform to certain of the

data elicited by Denny Brown and Robertson. From the combined data of these last two groups a high, low and average base line for normal intravesical pressure has been determined. (Figure 5C) Attention should be particularly directed to the shape of the curve and more especially to its rise through a series of steps. The degree of tonus set up in response to a minimum fill is also both characteristic and important. These factors together with uniphasic, more or less regularly spaced or tetanic contractions with plateau tops occurring in the

on the part of the patient especially if it takes the form of physical activity. This will produce sudden rises and falls of the fluid level in the manometer (figure 6B), which if observed carelessly may be interpreted as detrusor contractions. More careful study will demonstrate, however, that they lack the plateau at the apex which is an essential part of a true contraction and also do not show any steppage in either the rise or fall. They are due to sudden contractions of the muscles of the anterior abdominal wall and are the graphic evidence of

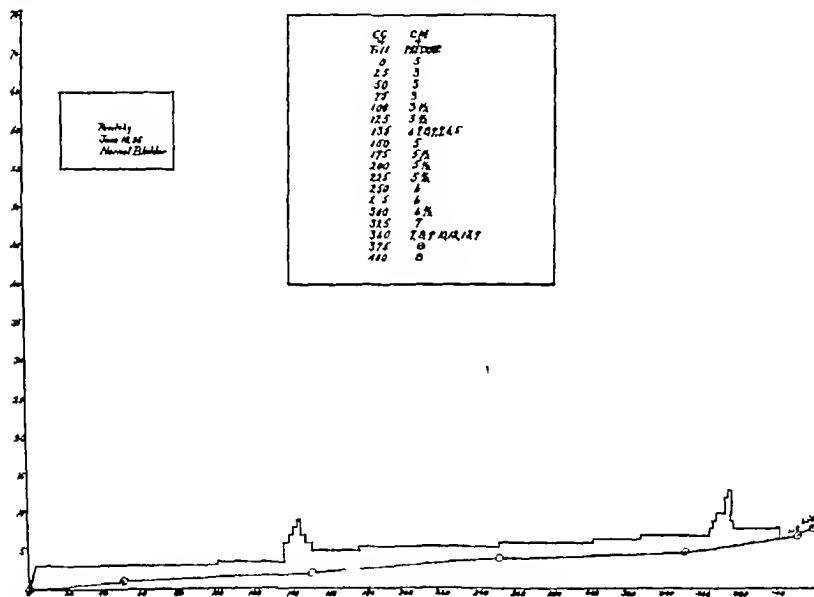

FIGURE 4

absence of postural or psychologic inhibitions characterize the normal human detrusor muscular activity.

Artificial Variations There are two common artifacts that, unless recognized, may confuse the interpretation of the graphs. The first has to do with the rate at which the bladder is filled during the test. (Figure 6A) This may produce an artificially high level for the base line and will completely obscure the normal step appearance that goes with increasing fill. Inasmuch as these variations may both be symptoms of interference with the normal vesical neuromuscular reflex, particularly in certain spinal cord diseases or injuries, it is important to identify the cause of their appearance accurately. The second is due to lack of cooperation

an increase in intra abdominal pressure transmitted directly through the bladder and its contents.

It is not appropriate at this time to consider the various other graphs that are associated with bladder pathology. However for purposes of record it can be stated that with this apparatus it has been possible to differentiate acute cystitis, a contracted hypertonic bladder, a non contracted hypertonic bladder, a completely atonic bladder, destructive disease such as carcinoma of the wall of the bladder and finally the different stages of resumption of bladder function after spinal cord injuries.

Discussion A detailed review of the studies which have led to our present understanding of the physiology of micturition cannot

be undertaken in this place Suffice it to say that available knowledge is much greater than is commonly made use of Experimental and other work done by such men as Learmonth¹, Holmes⁵, Qunby⁶, Graves and Davidoff⁷, Graves⁸, Langworthy et al^{9 10} and many others have cleared up many of the broader problems Finally Denny-Brown and Robertson² with an ingenious and extraordinarily accurate apparatus have, with the help of normal human subjects, dealt with and settled many of the hitherto misunderstood details The result of all

sphincter serves in its turn as a sensory impulse which again travels to the sacral segments of the spinal cord to leave as a motor impulse by way of the efferent side of a second reflex arc which this time includes the pudic nerves This final impulse relaxes the external urethral sphincter This activity is all mediated through normal neurological connections that lie wholly in the lower segmental levels of the central nervous system It provides for the emptying of a given bladder in response to the purely automatic impulse elic-

FIGURE 5

this work may be summed up as follows Micturition takes place because of the reflex contraction of the detrusor muscle accompanied simultaneously by a reciprocal relaxation of the internal urethral sphincter and followed by a further reflex relaxation of the external sphincter This succession of events is started by a sensory impulse derived from a given amount of stretch of the bladder wall This impulse reaches the sacral segments of the spinal cord by way of parasympathetic or pelvic nerves, is shunted in the cord to the motor neurone of this reflex arc and reaches the detrusor and internal sphincter musculature simultaneously as a motor impulse As noted above, this produces contraction of the former and relaxation of the latter This relaxation of the internal

is initiated by a given amount of stretch of that particular bladder wall If this constituted the whole story, however, the vesical storage facilities would be limited below known normal levels This greater storage capacity is provided through the control of what would otherwise be emptying contractions of the bladder wall, by the impact of inhibitory impulses originated at suprasegmental levels These impulses find their origin in unusual or inconvenient psychological or postural circumstances They pass down the cord to act probably on the afferent part of the parasympathetic reflex arc As a result, relatively great degrees of vesical distention may be reached before the urgency of the reflex detrusor contraction results in emptying This storage capacity may be still fur

ther increased by the voluntary contraction of the external sphincter. This can be imposed at will on the reflex relaxation that would otherwise take place. As a corollary to this it becomes apparent that facilitation of micturition is attained only by the control of the inhibitory impulses from the higher central nervous system levels. Only in this way can the underlying reflex activity leading to emptying resume its normal rhythm. It is furthermore true that relaxation of the external sphincter takes place only reflexly. The functions served by the

cause my observations were made with a method of fill that approximated the normal. They were both isotonic and isometric in type. On the other hand direct observations were made of the detrusor contractions only and do not include any sphincteric data that is other than inferential. They demonstrate again that the bladder distends by periods of stretch which are brought to a close by the imposition of contraction waves. This stretch occurs in the presence of a fundamental basic tonus, while the contractions raise the level of this fundamental

FIGURE 4

sympathetic connections are still in dispute with no final evidence available one way or another. Also in doubt is the presence of an autonomic plexus analogous to Auerbach's plexus and lying wholly within the limits of the vesical wall. What evidence there is, however, is to the effect that this structure if present, functions only in the event of an otherwise complete denervation of the entire bladder and its sphincters.

The data outlined above and obtained as described from the study of thirty one normal bladders strongly confirm this summary of the physiology of micturition. They also agree with that obtained with more accuracy though from fewer individuals by Denny Brown and Robertson. This is the more significant be-

cause my observations were made with a method of fill that approximated the normal. They were both isotonic and isometric in type. On the other hand direct observations were made of the detrusor contractions only and do not include any sphincteric data that is other than inferential. They demonstrate again that the bladder distends by periods of stretch which are brought to a close by the imposition of contraction waves. This stretch occurs in the presence of a fundamental basic tonus, while the contractions raise the level of this fundamental

cause or until, because of pain in or overdilatation of the bladder, the motor response no longer remains under control. This is succeeded by a tetanic type of contraction which lasts until the excessive dilatation has been reduced to a level where the inhibitory factors can again assume control.

While no direct evidence of sphincteric action is available as the result of this work it can be assumed with safety that the similarity between these findings and those of Denny-Brown and Robertson as regards the detrusor action justifies the conclusion that here too detrusor contraction was accompanied by reciprocal sphincter relaxation. In addition it is certain that in all these cases voluntary control of the contraction of the external sphincter was easily demonstrable at the time of catheterization. Furthermore anal and glans reflexes, the pathways for which are known to lie in the pudic nerves, were also always active. This would seem to imply that the reflex which led to relaxation of the external sphincter following detrusor contraction was also normal and active inasmuch as the same anatomical connections with the spinal cord were involved.

These data give no information regarding the impulses that traverse the sympathetic system connections per se and offer neither confirmation nor denial of the presence of an autonomic intravesical plexus.

CONCLUSIONS

- 1 A simple inexpensive portable cystometer is described.
- 2 Simultaneous readings of approximate content of the bladder and intravesical pressure, when made with this cystometer, give sufficiently accurate information about the activity of the detrusor muscle and the internal urethral sphincter to identify any deviations from normal.
- 3 When properly charted on coordinate paper of a sufficient size these figures will provide a graph of this activity.
- 4 Normal involuntary reflex activity of the external urethral sphincter can be checked by the activity of the anal and glans reflexes. It parallels that of the internal sphincter.
- 5 The normal ability of the patient voluntarily to contract the external sphincter can be measured by his resistance to the passage of a urethral catheter.
- 6 Normal detrusor activity must approximate the following requirements:

- (a) The initial tonus of the detrusor muscle set up in response to less than 10 cc of content will vary from $\frac{1}{2}$ to 5 cm of water pressure.
- (b) Distention of the bladder proceeds against a background of tonus which is constantly being increased by additional increments added by means of waves of contraction that vary from the lowest possible level to heights that will produce complete emptying.
- (c) This basic level does not normally rise above 15 cm of water with the first 400 cc of fill.
- (d) Emptying contractions are uniphasic with a plateau at their apices.
- (e) While normal bladder activity is fundamentally a function of a pure spinal segmental reflex arc it can be inhibited up to the point of detrusor tetany by impulses from suprasegmental levels. These impulses are set up as the result of unfavorable postural or psychological influences, or by voluntary contraction of the external urethral sphincter.

7 Graphs of normal bladder activity made with this cystometer fall into three types: (a) one in which spaced emptying contractions occur throughout the experiment, (b) one in which emptying contractions occur toward the end of a fill of 400 cc in the form of unspaced constant tetanic contractions and (c) one in which during a fill of 400 cc there is a complete absence of emptying contractions.

8 Facilitation of micturition depends in part at least upon the repression of conscious and unconscious inhibitions. This permits the normal underlying reflex activity to resume its rhythm.

NEW HAMPSHIRE MEDICAL SOCIETY

MANAGEMENT OF SKULL FRACTURES*

How Can the High Mortality Rate Be Reduced?

BY HARRY E. MOOK, M.D.†

IN a previous publication‡ the author has shown that at least 125,000 proved skull fractures occur annually throughout the United States. The mounting casualty rate from automobile accidents during the last five years has undoubtedly raised this number to more nearly 150,000 skull fractures per year. Wherever trains run, automobiles are driven, airplanes fly, horses are ridden or stairways are built, there you may have skull fractures. The victims of this trauma frequent our smallest as well as our largest, hospitals. In fact, I have knowledge of certain small but well equipped hospitals located near extremely busy thorough highways where the number of skull fractures treated exceeded the number in certain of our well established neurosurgical centers. Thus it is evident that skull fractures constitute a problem for the general physician and surgeon as well as for the neurological surgeon. It was this fact, combined with the location of our hospital, permitting the development of a large traumatic service that caused this problem to become my chief surgical hobby. The gradual but steady reduction in the mortality rate which is being reported from a constantly increasing number of clinics, both from neurosurgeons and general surgeons, shows that the campaign for better management of skull fractures is succeeding.

The term "skull fractures" rather than "head injuries" is used purposely by the author but it must be emphasized that *de la cranial, cerebral, or craniocerebral*, the treatment of the injury is identical. The fact cannot be overemphasized that a given head injury without any x-ray or other evidence of skull fracture, may require just as close observation just as pains taking management, and even then may prove fatal.

However, no uniform statistical study of this problem can ever be made if "Head Injuries" is the basis of reporting cases. One man's judgment as to the seriousness of a head injury before it should be included as a "possible clinical skull fracture" differs materially from another's judgment. The mortality rate is the best measuring rod for gauging the results of

treatment and whether advances are being made in treatment. Thus, if one author builds up his statistics on absolutely proved skull fractures, his mortality rate will be more favorable, because many head injuries which are practically positively proved skull fractures will die before absolute proof is obtained. Again, if an author includes a large number of head injury cases in his statistics because he feels that they are clinical skull fractures, his mortality rate will likewise be more favorable, because the death rate in several large series of head injury cases without fractures has proved to be considerably lower than when fractures existed. On the other hand, if an author includes in his statistical study not only his definitely proved skull fractures, but from 3 per cent to 10 per cent of cases dying before proof can be obtained but which are so positively clinical skull fractures that they must be thus classified, then it is evident that a truer, although higher, mortality rate will result.

In the years 1931 to 1934 inclusive the author presented a Skull Fracture Exhibit in the Scientific Exhibits of the American Medical Association. In the first Exhibit at Philadelphia in 1931 he presented 100 consecutive cases of proved skull fractures from his own clinic at St. Luke's Hospital. At that meeting and at subsequent meetings many physicians and surgeons throughout the country, many of them from your New England States, consented to cooperate with him by reporting their consecutive skull fracture cases on a common blank furnished by the author. Likewise several hospitals reported their cases and six hospitals allowed the author and his two associates, Dr. Reed Morrow and Dr. Charles Shannon, to study their consecutive head injury files for a period of five years, in order to select the proved skull fracture cases. The facts and impressions presented in this article therefore have been gleaned from a study of 2595 cases of positively proved or practically positively proved skull fractures collected from the following sources:

- 1 Two hundred cases of skull fractures entered on the author's service at St. Luke's Hospital. Ninety-two per cent of all these were positively proved skull fractures. The remaining cases were so obviously skull fractures that they had to be included although they raised the death rate 3 per cent.

Read at the Annual Meeting of the New Hampshire Medical Society at Manchester May 4, 1935.

*Mock, Harry E.—Senior Attending Surgeon, St. Luke's Hospital. For record and address of author see "This Week's Issue," page 612.

‡Management of skull fractures and intracranial injuries. J. A. M. A. 97:1159 (Nov. 14) 1931.

- 2 Eight hundred and fifty cases collected from approximately 100 individual surgeons and twelve hospital staffs reporting on a uniform blank prepared and sent to them, approximately 1250 cases were submitted as skull fractures, but 400 of these were ruled out, as they did not fulfill our requirements for positively proved or practically positively proved skull fractures
- 3 Thirteen hundred and fifty-four cases were obtained from a survey of the records of six hospitals covering a period of five years in each hospital. Approximately 5,000 records were studied, and from these were culled the 1354 cases of positively proved or practically positively proved skull fractures
- 4 One hundred and ninety-one cases were submitted to us from the neurological service of a large hospital

These cases fulfilled the requirements for proved skull fractures

My address given before your Society last May was built around forty-two lantern slides which enabled me to demonstrate my subject more clearly. Space will not permit the reproduction of all this material, therefore I wish to devote this article to that portion of my address which dealt with the question—“*How Can the Mortality Rate from Skull Fractures be Reduced?*” In order to develop this subject it is necessary to reproduce just two of those lantern slides

CHART A

HOW CAN HIGH MORTALITY RATE BE REDUCED?

A—IN FIRST 24 HOURS

45% of Deaths Occur in 1st 24 Hours

- 1—Greater knowledge concerning early management by rank and file of profession
 - a—Laity education—prevention and 1st aid
- 2—Treat shock first—everything else can wait
 - a—Don't suture lacerations at once
 - b—Don't reduce fractures at once
 - c—Exception—a severe life threatening hemorrhage
 - d—Least possible moving of patient chief essential
- 3—Every serious head injury is emergency case
 - a—Requires immediate attention of attending physician
 - b—Early skillful examination—blood and urine
- 4—Don't overlook less obvious, often more serious, associated injury
 - a—Two cases ruptured spleen—operated—lived

- 5—X-ray every head injury—but don't x ray
 - a—In presence of shock.
 - b—In presence of delirium or deep coma
- 6—Immediate operation of Skull Fracture seldom indicated
 - a—30 immediate operations—28 deaths
 - b—15 subtemporal decompressions in 1st 7 hours—15 deaths
- 7—Treat every head injury as serious until proved otherwise
- 8—Morphine lulls the surgeon, as well as the patient, to sleep

The following table shows the source of my figures for the above chart, as well as for chart B

TABLE 1				
Source	Number	Total Death Rate	Death Rate 1st 24 Hours	Death Rate 1st 7 Days
Mock's cases	200	18.2%	46%	38%
Collected cases	850	26%	44%	42%
Hospital Records	1354	40.5%	45.5%	41%

After all is said and done the answer to this question of, “How can the high mortality rate from skull fractures be reduced?” has been the chief concern of the Skull Fracture Exhibit, as well as the chief motive behind the efforts of all men working and teaching in this field of head injuries. Recently I came across an unprinted monograph by Dr. Nicholas Senn, written in longhand in 1896. In this article he stressed the fact that skull fracture was a widespread condition which must more often be treated by the general physician rather than by surgical specialists. He pointed out that the early management of these cases, before a special surgeon could arrive on the scene, often spelled life or death for the patient. In other literature of his day there was a note of inevitableness in the discussion of the mortality rate from head injuries. During the last decade the attitude toward this condition has been more hopeful and without question, many suggestions in management have been made which, if adopted and logically carried out, have been and will be life saving measures.

In recent years, it seems that a note of pessimism has crept into some of the articles, and again the inevitableness of death in a certain percentage of skull fracture cases is being stressed. For example, Dr. Walter Dandy (*J. A. M. A.* 101:774 [Sept. 2] 1933) states “Give nature a chance and 70 per cent of all patients with severe (head) injuries will recover spontaneously. If left alone, the remaining 30 per cent will die. From this group perhaps one

third (one tenth of the total injuries) can be saved by subtemporal decompression if well timed and properly performed. The remaining 20 per cent (of the total) must be regarded as beyond redemption by any rational means available.

If it were possible to pick out the inevitable deaths, or those that remain beyond redemption by any rational means, the situation would be ideal. It would then be simply a matter of concentrating upon the other 80 per cent. Time and again, in commenting upon one of our deaths from skull fractures, we have found ourselves saying "Well, that was an inevitable death, nothing could have saved him." Time and again we have thusly predicted concerning a certain patient but have continued to fight and, to our surprise, the patient has recovered. It is simply impossible for any man so to classify all skull fracture injuries that the profession can select the cases of inevitable death and the cases that might be saved. This being true our attitude must be hopeful watchful constantly searching for greater knowledge especially in the management of the early cases the time period in which the death rate is the highest.

There is great need here for education of the laity especially first-aid and prevention methods. Without question the states must develop uniform laws which will control the types of automobile drivers, standards of ability for the drivers, uniform traffic regulations, especially speed control, and compulsory insurance that will provide hospital and medical attention from the very minute an accident occurs. During A Century of Progress I gave an address on Skull Fractures for the College of Surgeons at one of their public meetings. I know from the testimony of two persons who heard the discourse that on two different occasions each prevented the dumping of an unconscious patient with a skull fracture into the rear seat of an automobile for the purpose of conduction to a hospital. They covered these patients up, kept them warm and insisted upon an ambulance for transportation. Talks of this nature should be given all over the country to lay audiences. Better and more complete ambulance service must be established everywhere. The profession must join with the laity in a fight, first, against accidents and secondly, for better emergency and subsequent care when trauma occurs.

The second point in Chart A viz treat shock first—everything else can wait is a commonsense but life-saving slogan where skull fractures are concerned. Not so often now as formerly, we have witnessed these skull fracture cases brought into the emergency room at the hospital unconscious and covered with blood which has oozed from the ugly scalp wound. The patient is cold and clammy and in coma or at other times

is fighting in delirium. The interne or doctor in attendance shows a one track mind when he pays attention to this laceration. Time and again we have witnessed such a patient in deep shock, with two or three people restraining him while the attending physician proceeds to shave his scalp and suture the laceration. After this is completed, the patient is moved to the hospital bed, occasionally to the x ray laboratory first, yet most of us have learned not to x ray these cases at once. It is of equal or greater importance not to delay the treatment of shock while the laceration is sutured. Formerly we had in Chicago a hospital devoted solely to emergency treatment. None of the patients were kept in this hospital all night. I have seen several cases transferred from this hospital to St. Luke's while in shock and coma but with their scalp wound sutured. Two cases thus transferred developed a marked erysipelas while several cases developed scalp infections from the immediate suturing of the scalp wound. It is not only the best treatment to treat the shock first and suture the laceration later but it is better treatment to suture the laceration after one has had a better chance to cleanse it and debride it and to make sure that a compound fracture does not exist.

The following case illustrates "b" under 2 in chart A viz., the immediate reduction of fractures in the presence of skull fracture and shock.

Mr. B. was admitted to one of our best hospitals in coma and apparently with a head injury and a fractured femur. For the shock he was given a hypodermic of morphine at once. He was then taken from the emergency room to the x ray laboratory where an x ray of both the skull and the femur were made. Both showed fractures. The fragments of the femur showed little displacement and would require little manipulation and anyway the patient was in coma and would feel nothing. He was therefore taken to the nearby plaster room where a body and leg cast was applied. He was then moved to his hospital room. He was then in even greater shock, likewise he was extremely restless. Therefore another hypodermic of morphine was given. When this patient was seen by one of our best neurological surgeons one hour later the patient had Cheyne-Stokes respiration, a rapid thready pulse and died shortly after the specialist completed his examination.

Fractures can so readily be immobilized in a pillow splint or blanket splint or a Thomas splint, or even by a board splint that immediate manipulation and reduction or more elaborate splinting is never necessary or indicated when a skull fracture is suspected or when the patient is in shock be it general shock from a fracture or cerebral shock from the head injury. Ob servance of this fact will save many lives.

Only occasionally is there a severe life threatening hemorrhage which requires the immediate attention of the surgeon, even in the presence of the shock. I have never observed a middle

meningeal or subdural hemorrhage that gave signs or symptoms of its presence to the extent that surgical intervention was necessary during the first few hours following the injury when the shock period is present

The least possible moving of the patient is the chief essential in the presence of head injury, and especially when cerebral shock is present. In the author's 200 cases of skull fracture, shock in varying degrees was present in 90 per cent of the cases. I have seen it recently written that shock was not usually present in head injuries. This is not true, for in head injury sufficiently serious to cause the least disturbance of consciousness, shock is usually present. Remember, that it differs from the general picture of shock in that, added to this are the cerebral disturbances which cause respiratory depression, fluctuations in pulse rate and blood pressure, as well as the anoxemia peculiar to both general and cerebral shock. The following example best illustrates this point concerning moving the patient.

A young Jewish girl was admitted to the ward at St. Luke's Hospital in coma and with a definite head injury. Most of these serious head injury cases are first admitted to the ward. Many of them can afford and insist upon being moved to a private room. This move is never made with my consent until the shock has been combated and until the moving of the patient will not add insult to the injury. In this case, the parents insisted upon immediate removal to a private room. Upon my refusal to move her the family surgeon was called in on the case. He immediately ordered an x-ray which was made. When she returned from the x-ray room she was extremely restless and a hypodermic of morphine was given. Meanwhile, the family had arranged for a private room and the patient was at once moved to a distant part of the hospital to this private room. She died one hour later. This was not a case that could even be classified as an inevitable death. Unquestionably, the early moving of this patient was responsible for the disaster.

A physician who visited the Skull Fracture Exhibit in Philadelphia in 1931 and again visited the Exhibit in New Orleans in 1932 told me the following story. He practiced in a small village fifteen miles from the county seat where the hospital was located. One of the busiest through highways passed through his village where many accidents occurred. Prior to 1931 he was in the habit of rushing these accident cases, including his skull fracture cases, over to the county seat hospital. After listening to the first Skull Fracture Exhibit he changed his tactics. He stated that during the last year he had treated six head injury cases in his home, from a few hours to several days, before subjecting them to the long trip to the hospital. All six of these cases recovered whereas in the previous year all of his skull fracture cases died.

At the Skull Fracture Exhibit in Cleveland, at least five surgeons told me of treating skull fracture cases in nearby farmhouses for two days to three weeks before moving them into

town to the hospital. One physician, discussing one of my early papers on Skull Fracture at Logansport, Ind. stated "It will please the essayist to know that I have a skull fracture case out here in the country about eighteen miles. The accident happened ten days ago and I moved her into the nearest farmhouse. She is still alive and everybody is happy except the farmer. I won't move that girl until I know it is safe."

The above examples led to the development of my slogan—"A LIVE SKULL FRACTURE IN A FARMHOUSE IS BETTER THAN A DEAD ONE IN THE HOSPITAL."

Every serious head injury is an emergency case. No conscientious surgeon today neglects to respond immediately to a call from a patient, or from his interne, concerning a case of acute abdominal pain radiating toward the right lower quadrant. We have become thoroughly imbued with the emergency nature of acute appendicitis. It is just as essential to respond to the call concerning an acute head injury. Yet in reviewing the skull fracture cases from the records of six hospitals it was noteworthy that many a case admitted at night was not seen by the attending man until some time the next day. Several cases died before the attending surgeon's visits—one as long as twenty-eight hours after admission.

When should a head injury be considered serious and therefore an emergency case? Several conditions are here involved, chiefly the following:

- (a) When the head injury, although apparently trivial, has occurred in a serious accident with potentialities of great damage.
- (b) When there has been a loss of consciousness.
- (c) When the case is sufficiently serious to be admitted to the hospital.

No matter what time of the day or night the call comes the physician or surgeon responsible for the case, or an experienced assistant if he has one, must immediately see that head injury case. He must make a careful, skillful examination without unduly disturbing the patient. He must look for associated injuries. The urine (catheterized specimen if impossible to obtain otherwise) and the blood must be examined. Why? Because occasionally the urine is bloody indicating the ruptured kidney or bladder, or the leucocyte count is high suggesting the possibility of an internal abdominal injury. The surgeon with his experience is better able to judge whether the trivial injury case needs to remain in the hospital. This decision should never be left to the interne. The surgeon should be the one to determine whether the case is able to be x-rayed at once. He should direct the treatment of the shock. He should remember that 45 per cent of his cases will die in the first

seven hours and therefore his close observation and direction of the treatment is needed most during this period. May the sleep of any of us be terribly disturbed if we fail to respond immediately to the call of the head injury case!

Many are the examples which I have collected, some in my own practice, illustrating the need of emphasizing these rules concerning the emergency nature of the head injury case.

- (a) There was the case admitted to my service at three A.M. This patient, male, forty-five was stuporous but the interne could smell alcohol on his breath and felt he was drunk. The slight bump on the head seemed trivial. He was new on the service and we had failed to instruct him in the rule to call one of us on every head injury case (mistake 1). I was signed up to operate at eight A.M. and therefore did not visit this patient as soon as I reached the hospital (mistake 2). A blood count was made early that morning but of course I did not know that it was 6000 whites because of failure to visit the ward (mistake 3). At eleven A.M. the nurse phoned the operating room that the patient seemed to be dying. We hurried to the ward and found the patient in extreme shock, blood pressure 48 and pulse barely perceptible. Examination showed a rigid abdomen, dullness in left flank. The leucocyte count was now 36000. A diagnosis of ruptured spleen was made. In spite of the serious condition of the patient I operated and removed a badly ruptured spleen. Preparations had been completed for a blood transfusion and this was done at once. A second transfusion was given at eight P.M. This patient made an excellent recovery. There were no signs of a skull fracture at any time other than the unconsciousness. However at the end of two weeks an x-ray of the skull showed an extensive linear skull fracture.

The failure to observe the "rules of the game" almost cost this patient's life.

- (b) A serious automobile accident occurred. A husband and wife and their five-year-old boy were in the car. They were brought to a hospital and hurriedly examined. The boy was not hurt apparently. He sat on a chair in the waiting room while x-rays were made of the mother and father both of whom had minor fractures, one of the clavicle and the other of the hand. No one paid further attention to the boy. The father and mother had been treated and were about to depart when the boy suddenly fell off the chair unconscious. He soon regained consciousness but could not talk and soon developed a paresis in the right arm and later in the leg. I was called diagnosed a middle meningeal hemorrhage, operated and found the same. The boy recovered.

This case shows how easily the true condition in the boy's case was overlooked and the potentialities of a catastrophe which existed if he had been allowed to depart.

- (c) One of my senior medical students was externing at a small hospital at night. A boy was brought in about eight P.M. having been struck by an automobile and knocked completely across the street. He had a scalp wound but

otherwise seemed unharmed. The surgeon who ran this hospital examined the boy and then told the extern to suture the scalp and let the father take his boy home. It was a "hit and run" accident, the family was very poor and no one could be financially responsible for the case. The extern's suggestion regarding keeping the boy in the hospital under observation was therefore rejected with the excuse that "these kids are tough and be it as hurt." About three A.M. the father came to the hospital stating that his boy was acting normal and breathing normally. The extern went to the home found the boy stuporous, slowed pulse and with stertorous breathing. He helped the father carry him to the hospital and the surgeon was called. Because of lack of financial means a police ambulance was called and the boy was transferred to the county hospital. He died a few hours after admission from an obvious middle meningeal hemorrhage and without the benefit of surgical intervention.

Mistake 1 Failure to keep under observation the apparently trivial injury from a serious accident.

Mistake 2 Undue transportation of the case.

Mistake 3 The apathy of the public and of the profession in not long since demanding a commonsense law which would compel all county commissioners to pay these small, poorly endowed hospitals to keep such patients as this boy and similar emergency cases, until it was safe to transfer them to the county hospital. They could at least pay a rate commensurate to the cost of caring for the case in the county hospital.

- (d) There is the case of the airplane pilot who crashed with four passengers. He helped get the injured from the wreck and helped to take them to the hospital where all were admitted, treated, and recovered. He only had a scalp wound which was sutured and he was allowed to depart. That night he became unconscious in his hotel room was not discovered until morning and died before they could get him to the hospital.

At least twenty examples have been collected of this type of head injury—scalp wound sutured, allowed to leave, later the cerebral damage manifested itself and death before anything could be done or death in spite of the efforts of delayed treatment.

If the reader is tired of examples remember that the author is endeavoring to emphasize how the high mortality rate from skull fractures can be reduced.

The skull fracture is often so obvious that it completely explains the extreme shock and deep coma that are present and persist until the patient dies. Even the coroner feels that the cause of death is quite obviously skull fracture and therefore refuses to do an autopsy. However in these days of terrific traffic accidents, with

their multiple injuries, one must never be satisfied with a diagnosis of skull fracture alone until by careful and repeated examinations he has ruled out the less obvious, but often fatal, injury. Many a case of so-called inevitable skull fracture death might have been saved if search for the less obvious injury had been made.

The author has had two cases of ruptured spleen occurring with proved skull fractures in which splenectomies were performed with recovery. Dr S W McArthur, at St Luke's Hospital, diagnosed a ruptured liver in a young lady four hours after admission with a skull fracture and with the patient in deep coma. He operated, found a badly lacerated liver, packed the wound, and this patient recovered.

A surgeon told me at the Cleveland convention of a skull fracture case which he treated for twenty-one days; the patient recovered and was allowed to go to his home in a small town twenty-eight miles away. A week later this patient suddenly became very ill and died within a few hours. The surgeon went to this home, performed an autopsy, and found a ruptured spleen as the cause of death. Delayed hemorrhage from a ruptured spleen is not uncommon.

There is no need to devote much space to emphasizing point 5 in chart A. I am convinced that in the past too many cases were sacrificed by the immediate rushing of the head injury case to the x-ray. No skull fracture, and for that matter no other fracture when the patient is in shock, should ever be x-rayed late, and as soon as safe, the x-ray should always be made, for it will prevent too early movement of an otherwise symptom-free patient, it will tell whether a depressed fracture is present and of a sufficient degree to warrant operative intervention, and it will show the location of the fracture, often a guide in both prognosis and treatment.

There are certain definite indications for operation in skull fractures as will be shown later. There are many borderline cases where it is extremely difficult to determine whether these indications are present. There are cases that are certainly nearing death where one feels that something surely can or must be done. The family is begging for action which fact often influences judgment. But from my own experience and from a review of the 850 cases reported to me and from a study of the 1354 hospital records one feels that this axiom holds true: *the immediate operation of a skull fracture, or the operation within a few hours, is seldom indicated.*

In my own experience there were three early cases operated, one five, and seven hours after injury, who were robbed of any chance they may have had for recovery.

From a study of the reports of cases sent me

by doctors from all over the country there were records of nineteen subtemporal decompressions, done within the first seven hours, with 100 per cent mortality.

From the hospital records, in spite of an exceedingly low operative rate, thirty cases of immediate operations were collected with twenty-eight deaths.

Dandy, who seems to favor operative treatment as the one definite thing that can be done in approximately 10 per cent of the cases, states emphatically that the longer the operation can be postponed the better the results.

Even in epidural or subdural hemorrhages the signs and symptoms of such conditions rarely develop within the first few hours. The author has had one case of middle meningeal hemorrhage that was definitely diagnosed and operated successfully six hours after the injury whereas in nine other cases, similarly diagnosed and successfully operated, the signs of this condition developed from two to thirteen days after the injury. As has been pointed out by Munro the signs and symptoms of subdural hematoma develop late as a rule.

Treat every head injury as serious until proved otherwise. This rule has been explained for the case which seems trivial and turns out seriously. On the other hand the rule does not mean that every head injury case must have a lumbar puncture or must be kept in the hospital for three weeks. In fact many of them are never hospitalized. But one should be quite positive, as a result of a careful neurological examination, that the patient is free of dangerous developments before deciding against hospitalization.

The majority of these questionable cases will turn out to be simple cases of concussion or possibly contusion—a differentiation often impossible to make. It is my habit to keep the less serious concussion case hospitalized and under observation at complete rest for one week, while the more serious, possibly contusion case is treated for ten days at least.

Morphine kills the surgeon, as well as the patient, to sleep. This is just as true in skull fractures as in appendicitis where most of us have learned to avoid this drug. In addition morphine is a respiratory depressant and this effect added to the respiratory depression so often present in head injuries is sufficient to be disastrous. A survey among a great many brain surgeons has developed the fact that practically none of them ever use morphine either in skull fractures or other cerebral conditions. Experience has taught them its dangers. General surgeons should be governed accordingly.

It is noteworthy that in the author's cases as well as in a study of the entire remaining 2395 cases 40 per cent of the deaths occurred

in the first seven days. Concentrating his every effort to reduce the mortality rate during this period, one gains impressions concerning therapeutic effects which, with the accumulation of data, gradually merge into facts. Proof of the merit in these facts comes with the gradual lowering of one's mortality rate. Furthermore, it is noteworthy that every man who has concentrated upon the management of the skull fracture case has witnessed this same lowering in his mortality rate. This is true in the case

CHART B.

HOW CAN HIGH MORTALITY
RATE BE REDUCED?

B—AFTER 24 HOURS

40% of Deaths Occur from 2nd to 7th Day

1—Greater knowledge concerning general management

- a—Dehydration started early (after shock) and persisted in will reduce fatalities
- b—Examine frequently—certain signs and symptoms interpreted correctly require life-saving special treatment

2—The earlier lumbar puncture is performed when indicated, the lower the death rate

- a—Not indicated in presence of grave shock
- b—Increased intracranial pressure—persisting after early dehydration—requires lumbar puncture

3—Repeating lumbar punctures when operation is indicated increases fatalities

- a—One case—coma punctured conscious convulsions 3rd day punctures repeated death 4th day autopsy subdural hemorrhage
- b—Six cases—definite focal signs 2 to 14 days repeated lumbar punctures all died autopsies in 3—middle meningeal hemorrhages.

4—8% of cases require operation

- a—Operative rate over 12% or below 6% in creases mortality rate
- b—The longer operation can be safely postponed the lower operative death rate
- c—Subtemporal decompressions seldom indicated—in 942 cases 27 such operations—22 deaths.

of the 150 physicians and surgeons who were sufficiently interested in the problem that they took the time to fill out the two-page skull fracture blank which we furnished them.

Temple Fay in his writings shows a reduction in his mortality rate from around 21 per cent to approximately 12 per cent in skull fractures and serious head injury cases.

George Swift in his writings and in personal communications shows a reduction in the mortality rate in the serious head injury cases cared for at Harbor View, Seattle, from around 35 per cent several years ago to 22 per cent five

years ago and finally to 12.1 per cent for the last three years.

The author, having built his statistics on proved or practically proved skull fractures, naturally has a somewhat higher death rate than the above authors. He has no statistics upon his death rate prior to 1925. But since that time concentrating upon the management of the skull fracture case, he published in 1931 a mortality rate of 20 per cent for proved skull fractures counting every case that entered his service even though death occurred one minute later. Now his mortality rate is down to 18.2 per cent for proved skull fracture cases. Counting skull fracture cases and some 500 serious cranio-cerebral injuries in addition his mortality rate is down to 11 per cent.

The author's experience as well as the testimony of many others working on this problem is sufficient proof that the serious head injury case need not be left to nature, that there are several well-defined therapeutic measures which can be applied to the management of these cases and finally that the high mortality rate can be reduced if greater knowledge concerning the general and special management of these cases is gained, especially by the rank and file of our profession who are seeing most of the cases.

Comparison of the above mortality rates with table 2 will soon convince one that there is need for greater knowledge concerning these therapeutic measures. In the six hospitals whose records were studied the cases were cared for by both neurological surgeons and general surgeons. In the 800 cases reported to the author the management was chiefly by general surgeons.

TABLE 2
FROM CHART FOR SKULL FRACTURE EXHIBIT
SHOWN IN 1934

Date and Source	No. of Cases	Mortality Rate
1927-1934 Mock's Series	171	19%
1928-1934 Collected Cases	800	26%
1928-1934 Hospital Records	1283	39%

What are the causes of death in these patients during the period between the second and the seventh days?

The great majority die from gradual respiratory and cardiac failure due undoubtedly to the cerebral damage. The next commonest cause for death is pneumonia. Meningitis in my experience causes less than 5 per cent of the deaths. Multiple injuries, diabetes, syphilis, alcoholism and old age are all marked contributing factors to the death rate.

In regard to meningitis, meticulous care of the bleeding ear avoiding antiseptic spraying or irrigation of the wound through any of the

sinuses and early, as soon as shock is over, débridement and cleansing of the compound fractures with loose closure of the wound will prevent many from developing this disease. When it does develop, early and frequent spinal drainage until the cell count is again practically normal, sometimes necessitating fifteen or more punctures, is the treatment to follow. The use of antimeningococcus serum in these cases is of no value unless the specific organism is the cause.

Don't mistake meningismus, from the irritation of blood the result of a subarachnoidal hemorrhage, for meningitis. When meningismus is present it is likewise an indication for repeated lumbar punctures.

One must always be on guard to detect the pneumonia case especially if the skull fracture patient is in the fifth decade of life or over. These patients, often stuporous or in coma, are left absolutely quiet on their backs for too long periods. Frequent change of position to avoid hypostatic congestion, often the forerunner of pneumonia, is important. The oxygen tent or inhalator is of the greatest value in many cases showing respiratory difficulty. I have seen patients who have been in coma for as long as two weeks and have not eaten a mouthful during that time. Patients have died from dehydration and starvation while in coma. This can be avoided and lives saved by the simple measure of passing a stomach tube and feeding the patient at frequent, regular intervals. Good nourishment is likewise a preventive of many complications including pneumonia.

The more specific therapeutic measures to prevent death from cerebral damage are outlined in chart B. The author has classified his cases in four groups according to signs, symptoms and treatment. These groups will be used to elucidate the therapeutic management.

GROUP I, or 5 per cent of the author's cases with proved skull fractures, required absolutely no other treatment except *rest in bed*. These cases were free of all signs and symptoms except the x-ray evidence.

GROUP II, or 55 per cent of the author's cases, required only general treatment. These were the cases requiring anything from shock treatment to a complete course of dehydration treatment except spinal drainage. All of these cases recovered except eight that died the first few hours in the hospital before any special treatment could be given.

Your attention is directed especially toward the cases requiring dehydration, a form of treatment in which the author agrees with many others. Its early (after shock has been overcome) and proper administration has undoubtedly saved many of these 55 per cent of cases from going over into the lumbar puncture or operative group.

The patient is usually in coma or extremely restless. His pulse and respiration are slowed but not usually below 55 and 16 respectively. The blood pressure, after the shock is over, is usually stable with a tendency for the diastolic reading to hover around 70. Of course in older individuals both systolic and diastolic may be elevated. The temperature is usually above normal, seldom above 101°. If a sedative is required chloral hydrate or sodium bromide per rectum is usually sufficient. Luminal or some similar preparation may be used. Morphine is avoided. It is surprising how many of these cases show a sedative response to the administration of a dehydrating dose of glucose intravenously.

Fifty cc of a 50 per cent glucose solution intravenously is administered to the patient with the above picture shortly after admission. It helps restore blood volume and thus aids in combating shock. If symptoms persist, this glucose solution is repeated in three to four hours. In addition, a saturated solution of magnesium sulphate, 4 oz., is now given per rectum providing shock is over. Many of these cases regain consciousness shortly after this and some require no further dehydration, while others will show periodical signs of returning increased intracranial pressure. To these, the dehydration methods are again applied.

A few of these cases will remain between coma and consciousness and will have persistently slowed pulse and respiration and often a lowered diastolic pressure. For these, the glucose solution and magnesium sulphate per rectum are administered every six to eight hours. Whenever dehydration is used, the fluid intake is limited to 20 or 30 oz. each twenty-four hours. If, in addition to this limitation of fluids, glucose and magnesium sulphate are repeatedly necessary, one must guard against overdehydration with its increased temperature, its restlessness, its headache and phenomena easily mistaken for cerebral damage symptoms. In 1931 the author pointed this out and offered the plan of easing up on the dehydration every forty-eight hours in order to *strike a balance*. More recently, Temple Fay has shown the need of guarding against overdehydration. Many cases have been carried along to recovery by this plan of dehydration treatment persisted in for two or more weeks. It is usually unnecessary to give other than the magnesium sulphate per rectum or by mouth once a day after the first week. Quiet surroundings, avoiding discussion of the case with the patient, good nourishment and rest in bed for three to four weeks complete the hospital care of this group. The period of convalescence will vary from six to twelve weeks.

GROUP III. Thirty per cent of the author's cases fell in this group, which is known as the Lumbar Puncture Group. It includes the

more serious skull fracture cases who, because of persistent coma, persistently slowed pulse and respiration, usually below 55 and 16, respectively, extreme restlessness, persistent, severe headaches, a lowered diastolic pressure, frequently down to 48, and any other signs suggestive of persistent increased intracranial pressure, do not yield to the usual dehydration procedure.

It requires the closest observation to detect the difference between the signs and symptoms due to cerebral edema and other causes of a milder form of increased intracranial pressure and the signs and symptoms of a threatened medullary compression due to more severe causes of increased pressure. A lumbar puncture done early, before medullary compression has developed, is often extremely spectacular in its results. Patients will frequently come out of a deep coma a few moments later and even converse with the doctor or nurse. In many of these cases, the puncture is only required once if the ordinary dehydration, above described, is persisted in.

Cases which have developed deeper coma, rapid, shallow respirations, with no grunt or Cheyne Stokes respiration and a rapid, bounding pulse, have definite signs of medullary compression. The lumbar puncture should have been performed before this stage was reached and certainly must be performed now. It is in these cases that this therapeutic measure is life saving, although many of these patients die in spite of this effort.

The importance of the pulse and respiration rate and of the blood pressure as a guide to treatment shows the necessity of hourly charting these, especially during the first day.

The lumbar puncture must be repeated if the signs and symptoms, which first indicate its need, recur or persist. In the case of a patient who remains alive for a few days, but is going downhill in spite of lumbar punctures and dehydration, one must search constantly for the least sign of an indication that operative intervention is needed. In the absence of all such focal signs, and where lumbar puncture has been thoroughly tried, it may be necessary to resort to an exploratory subtemporal decompression. Many lives are lost by persisting in lumbar punctures when indications for operative treatment are staring one in the face. (See 3 in chart B.)

GROUP IV, or the Operative Group. Ten per cent of the author's cases have fallen in this group. This may be a little high for the average run of cases, because several of these operations were performed in other hospitals when called in consultation.

The definite indications for operative intervention in skull fractures are the following:

A—Definitely depressed fractures. Many slightly depressed fractures give no symptoms and do not need operations.

B—The compound depressed skull fracture often with brain substance exuding from the wound.

C—Middle meningeal hemorrhages. Often these extradural hemorrhages are contraindicated to the site of injury. Rarely but it happens, the paralysis is on the same side as the clot. When such a phenomenon is present, and especially with the site of fracture shown by x ray opposite the site of the clot, the surgeon is presented with a condition requiring his keenest judgment. A bilateral craniotomy is usually the only answer.

D—Subdural hematoma. True blood clots are not always found at operation when this diagnosis is made. Frequently the condition is one of an encysted hematoma, containing only debris and serum. It is thought that the increased osmotic pressure within the thinly encapsulated cyst causes an increase of the fluid content, thus accounting for the late symptoms in subdural hematoma. Again, instead of a clot, one often finds a collection of cerebrospinal fluid. Sachs described this condition, explaining that it was due to a laceration in the arachnoid, thus allowing the escape of the fluid subdurally.

E—Subtemporal decompression. As a rule, this operation is now limited to those few cases with persistent symptoms, growing worse, not responding to lumbar punctures and with no definite focal signs. In my experience, it is not indicated in more than 1 per cent or 2 per cent of the cases.

It may be indicated to do the decompression at the site of the fracture. In such an instance, it is more in the nature of an exploratory craniotomy.

A fracture may be so severely depressed that an early x ray is indicated to evaluate the risk of delaying surgery. When the depression is extensive and the condition of the patient is such as to indicate that this pressure must be relieved, it may become necessary to operate even within the first few hours. Fortunately, such a situation seldom arises, but when it does, the operation may be life saving.

The operative rates in the various sources from which the 2,595 cases were collected were as follows:

A—In the 850 cases reported by surgeons to the author	11.6% operated
B—In the author's 200 cases	10.0%
C—In the 1,354 hospital records studied	3.3%

In the reported cases, it was evident that some surgeons were resorting to subtemporal decompression too readily, too early, and with a resulting higher mortality rate.

In a study of the hospital records, many cases were found where lumbar punctures were persisted in when signs and symptoms were present definitely indicating the need for operation. In one of the largest hospitals, the staff was proud of its conservative management of skull fracture cases, judged by its low operative rate. There was a time when the operative rate in skull fractures reached as high as 24 per cent (from author's study of the literature on head injuries from 1910 to 1920). In the following decade, many authors wrote on the conservative treatment of head injuries, stressing the non-operative treatment. They rendered a valuable service, because the reports in the literature from 1920 to 1928 showed the operative rate reduced to 12 per cent with a corresponding drop in the gross mortality rates reported in these articles from 49 per cent in the 1910-1920 period to 33 per cent in the latter period.

Today it would seem that the pendulum is swinging too far toward this so-called conservatism, and cases which definitely demand operative intervention are being neglected, with a corresponding rise in the mortality rate.

In conclusion, allow me to point out that during the last decade our medical literature has been so replete with controversial views concerning the management of acute craniocerebral injuries that the surgeon caring for only a few of these cases each year is left in doubt as to certain procedures. It has been said in condemnation that 90 per cent of the profession are using dehydration and lumbar punctures in head injuries. My studies lead me to believe that this is true. I am positive that 90 per cent of our profession would not persist in these methods if they were dangerous and of no life-saving value. Controversy concerning these two methods should be replaced by a united effort on the part of all workers in this field so to visualize conditions that the average surgeon in the average sized town will know when to use dehydration, when to institute spinal drainage, and when to resort to operative treatment.

The high mortality rate from skull fractures can be reduced by observing the commonsense principles herein set forth and by the proper

application of general and special therapeutic measures.

DISCUSSION

PRESIDENT LORD I shall ask Dr Emery Fitch to discuss this paper first.

DR EMERY M FITCH *Mr President and Gentlemen*—I am very glad that I was the one chosen from this Society to discuss Dr Mock's paper, because I have always breathed a sigh of relief when I felt the train pulling out of Chicago and I still had a whole head, and again because Dr Mock not only represents Chicago, but he represents a vast study of skull fractures all over the country and brings a message to us which we should heed. Another reason that I am glad to discuss this talk of Dr Mock's is because after going home from the New Hampshire Surgical Club last fall, having listened to Dr Munro, I felt that something definite should be done in our own little hospital, and other doctors who were there from our town felt the same way. So we corrected at once the bad habit of rushing head injury cases to the x ray room and rolling them over and over in our effort to get different views of the skull so that we could give a definite report to the newspapers as to whether that person had received a skull fracture. I should like to leave with you this message, that you work with your co-workers and try to head off this pernicious habit of rushing patients in shock to the x ray room just to get an accurate report to give to the newspapers. Really, it matters little what the newspaper knows about the condition of accident patients with head injuries, and we should treat them for shock before we take them to the x ray room.

We succeeded in getting an agreement among our men that before they tried to x ray the head injury cases, or the bad accident cases, whether head injury or not, they would first put them to bed and get them out of the initial automobile shock.

The matter of dehydration is enlightening to us all. It is something we can all do, regardless of whether we are surgeons, it is something that every doctor is now familiar with.

The matter of lumbar puncture, we feel, should be reserved for the time when the patient is not improving. We feel that the lumbar puncture should be checked by manometer reading and should not be persisted in just because we get bloody fluid.

I was glad that Dr Mock spoke about multiple injuries, because that, also, has been a pernicious habit in many of the hospitals, the doctors feeling that they must at once correct all the injuries, often at the expense of the patient's recovery. The other injuries can wait, we must get our patient out of the initial shock, if we are going to do them any good.

I was also glad to hear him speak of the cases that received a laceration of the brain, without necessarily a skull fracture. The fact that you are not able to read a skull fracture into your picture doesn't mean that you are permitted to neglect treatment of the head injury. You must take into consideration the symptoms and treat the brain laceration.

THE MECHANICS OF DELIVERY*

Especially As It Relates To Intracranial Hemorrhage

By FREDERICK C. IRVING, M.D.†

Mr. President and Members of the New Hampshire Medical Society

TO obtain an idea of the frequency of intracranial hemorrhage I have consulted the records for the past ten years of the Boston Lying in Hospital, as fairly representative of a large institution where about 2,000 infants are born annually. During this time there were 20,827 deliveries with an incidence of intracranial hemorrhage of 1 in 107 births. Since intracranial hemorrhage is not always a fatal disease, not all of these babies died. The diagnosis was made in many instances on the clinical signs alone, and could only be checked anatomically when an autopsy was performed. So far as the actual neonatal deaths from intracranial hemorrhage are concerned they have shown a steady drop from 1932, being 5.2 per 1000 in that year, 3.8 in 1933 and 2.5 in 1934.

A review of 182 autopsies on infants showed that 72 or 40 per cent, died from intracranial hemorrhage. Those who exhibited cerebral or cerebellar bleeding of a degree insufficient to cause death are not included in this number.

Intracranial hemorrhage may be due to trauma, intrauterine asphyxia or it may be a manifestation of hemorrhagic disease of the newborn. In the minds of many, however, the chief cause is violent or unskillful operative delivery either by forceps, internal podalic version or breech extraction. While deaths resulting from such procedures are far too frequent, they do not supply the entire casualty list in intracranial hemorrhage. In 40 per cent of our infants who presented at autopsy evidences of bleeding within the skull there were hemorrhages also in other parts of the body. The only logical inference then is that in almost half of these babies the intracranial hemorrhage was due not to trauma but either to asphyxia or to hemorrhagic disease of the newborn. Moreover, 25 per cent of our autopsy material showed petechial hemorrhages elsewhere in the body but none in the cranial cavity.

The production of petechial hemorrhages scattered throughout the various organs is a recognized pathological picture in asphyxia of the newborn. It is the duty of the obstetrician to recognize during labor the signs of approaching asphyxia and to take the proper steps to avoid the fatal results which may ensue to the infant. Auscultation of the fetal heart beats should be carried out at least every half hour

during the first stage of labor and at least every five minutes after the os is fully dilated and the expulsive phase has begun. Any marked slowing of the heart rate or any marked acceleration or any combination of the two or an irregularity in rhythm, is suggestive of disturbance in the gaseous exchange with the mother. Fair criteria of threatened asphyxia are consistent rates above 180 or below 100. Of the two a low rate is more important than a high one.

In the first stage of labor, especially if the membranes are unruptured, moderate alterations of the fetal heart rate are seldom of significance and do not call for interference. A notable exception, however, is prolapse of the cord. In the second stage of labor marked alterations in the fetal heart rate especially if accompanied by the passage of meconium, are of grave importance and indicate the termination of labor by the most appropriate and safest method which in the majority of cases, is by the low forceps operation. The passage of meconium stained liquor amnii on the other hand, is of no pathological importance.

Asphyxia may also result from a prolonged and unprogressive second stage of labor the fetal head being thrust for many hours against an unyielding perineum. In such cases a liberal episiotomy will often result in prompt expulsion of the fetus although in some instances it is necessary to supplement this small operation by the use of low forceps. The second stage of labor should never be made an endurance contest between the pelvic floor of the mother and the cerebral circulation of the infant.

The second cause of intracranial hemorrhage is hemorrhagic disease of the newborn. While the obstetrician can do nothing to prevent hemorrhagic disease he has the first opportunity to diagnose the condition and to begin its treatment. Bloody stools or vomitus may be present, as may petechial spots on the skin surface. A prolonged bleeding and clotting time are sometimes, but not always, found. Transfusion usually is of benefit but the intramuscular injection of blood usually exerts its influence too late to be of any aid.

The third cause of intracranial hemorrhage is trauma. Trauma may result from an attempt to deliver an infant which is too large through a pelvis which is too small. However cephalopelvic disproportion is not the most common cause of trauma since pelvic contraction occurs only about once in every 300 cases in New England. By far the most frequent source of fetal

*The second in a series of papers presented at the Symposium on Obstetrics at the Annual Meeting of the New Hampshire Medical Society at Manchester, May 7, 1935.

†Irving, Frederick C.—William Lambert Richardson Professor of Obstetrics, Harvard University Medical School. For record and address of author see "This Week's Issue" page 633.

cesarian section if the case had been followed by rectal examination. I do not believe in prolonged labor in the face of frank disproportion which may be detected by examination, nor do I believe in too prolonged labor against the rare intractable cervix, but I do believe that since the cardinal pathology of delivery infection is a septic focus in the split cervix, practically no operating should be done from below unless the cervix is fully dilated.

CONDITIONS CONTRIBUTING TO INFECTIONS

Certain general conditions in the patient and certain conditions specific to pregnancy seem to tend to increase the likelihood of infection. These are toxemia and nephritis, pyelitis, heart disease, and anemia, either that prone to occur in pregnancy or produced at delivery by blood loss as in placenta praevia and separation of the normally implanted placenta. Methods of delivery calculated to keep blood loss at a minimum, especially a deliberate and careful conduct of the third stage of labor, especially in these complications of pregnancy, is worth while. It is my opinion that even in well-conducted maternity centers too little attention is paid to the hemoglobin, red blood count and hematocrit. In the hospital after delivery each patient should have a count and hemoglobin. It is my belief that three million or less reds at this time calls for a transfusion, and that if the patient shows any elevation of temperature a transfusion should be given even though the count is three to three and one half million, and in some instances even if it is higher.

MASKING IN OBSTETRICS

It is considered that most epidemics of hospital sepsis and that most severe puerperal sepsis is the result of infection from the nose and throat. Very occasionally this appears to be autogenous, usually it is exogenous. It may take place at the time of labor or any time in the puerperium. It occurs equally by direct transmission of mouth and nose droplets, or by indirect digital transmission of the same. So it must be reasoned first that digital asepsis of a high order is as necessary for contacts—usually nurses giving perineal precautions—throughout the puerperium as in the delivery room. This is obviously an administrative problem. Incidentally it has often been found in puerperal hospital septic outbreaks that a failure to follow medical orders to the letter by the administrative heads of a hospital is completely or partially responsible for the epidemic. Secondly, Masking of the most effective type used faithfully over the nose as well as the mouth—and not around the neck, a place I have frequently seen the mask worn especially by pupil nurses—is absolutely essential both in the labor and delivery rooms and throughout the puerperium during contacts. It has been shown experimen-

tally that a mask becomes wet on the outside in about ten minutes and transmits organisms to petri dishes some distance away if the subject of the experiment talks or coughs. Therefore it is my practice to double mask if I have a cold at time of delivery and in any event to conduct delivery or abdominal section without talk. If ordeals or discussion or coughing are imperative, the face should be turned away for the time being. If a mask becomes visibly moist on the outside another may be tied over it. Nurses should be made to carry out perineal precautions in silence. It is usually true that nurse-borne epidemics of throat-borne sepsis may be attributed to an individual who has had a fairly recent *acute* upper respiratory attack sufficient to put her off duty for a few days. Hence such nurses must not be allowed to return to obstetrical duty until cultures show the throat and nose negative for hemolytic streptococci. The wider use of throat cultures should be used in so far as it is practical, but dry masking and silence will prevent much present-day severe puerperal infections from the nursing service.

EXPERIENCE WITH OTHER METHODS OF INFECTION

We have seen two patients die infected apparently by perineal icebags supposedly sterilized after contact with a case of streptococcus uterine sepsis of undetermined origin who recovered, showing the commonly seen increased virulence of the organism as it is passed through other victims. For this reason we have abandoned the use of the perineal icebag entirely. We have some reason to believe that solutions of one sort or another used to paint perineal stitches for comfort or supposed antisepsis have transmitted infection so the use of these we have abandoned. We use opium suppositories $\frac{1}{2}$ to 1 grain in the rectum for perineal comfort.

We have seen two cesarian sections die of peritonitis, operated the same summer week in the same institution with the same rare infecting organism apparently from dropped perspiration of one man who took part in both operations. No other sepsis was present at the time. We therefore set the rule that one nurse in the operating room is assigned to "watch for and mop sweat" on sight—irrespective of the momentary feelings of the operator, and make her entirely responsible for this. It is not reasonable to expect the surgeon and others in the operating room to do "sweat detection" in addition to other duties.

TREATMENT

The scope of this paper calls for little or no comment in respect to treatment of puerperal infection. In the future and where at present available, "immune transfusion" gives the only specific hope ever offered to these patients except the difference in virulence of the various

organisms and the patient's own individual resistance. Simple transfusion, especially in relation to the blood picture, often repeated, general supportive measures including rest, and the drainage of frank pus when it reaches the surface per vaginam or otherwise are at present our only remedies. Therefore prophylaxis should be our aim.

SUMMARY

Digital asepsis in labor and throughout the puerperium, dry masking and silence throughout the same periods, cultural watching of nasopharyngeal suspects, *an object respect for the integrity of the cervix by the physician* care of the potentialities for infection at time of delivery from the urinary tract, an accurate knowledge of the blood picture after labor and at other times if it seems wise, appropriate and immediate correction of this picture if it is a poor one abandonment of perineal icebags and "perineal solutions," and a scrupulous regard of operating room technique including the 'sweat risk' constitute the sum of this prophylaxis. Carried out in careful detail I believe a highly creditable reduction in maternal mortality and morbidity from puerperal sepsis can confidently be expected.

MISCELLANY

LEONARD JARVIS M.D.

Dr Leonard Jarvis, for fifty-two years a practicing physician in Claremont, as were his father and grandfather before him died on January 28 1936 at his suite at the Hotel Moody. He was eighty-three years old and for several years had been in failing health continuing however up to within a few days of his death the practice of the profession to which his life had been devoted. Taken critically ill the previous week he failed to rally and death claimed Claremont's best loved citizen.

Dr Jarvis was born in Claremont on July 29 1853, son of Dr Samuel and Sarah Jarvis and grand son of Dr Leonard Jarvis. He was graduated from Kimball Union Academy in 1869 from Dartmouth Medical College in 1873 and received his medical degree from Harvard in 1882. After serving internships in Boston and Providence he returned to Claremont in 1884 to engage in practice there.

On June 25 1893 he married Miss Mabel Howard of Providence R. I. To them were born two children, a daughter Caroline who died in 1906 and a son Samuel Gardner Jarvis.

Dr Jarvis was a member of the American Medical Association and of the New Hampshire Medical Society being publicly cited by the latter organization in May 1932 as one of the five Granite State physicians who had served continuously for half a century. Two years later on May 16 1934, he was

the recipient of the Society's highest award the fifty-year gold medal.

Dr Jarvis was for many years a director of the Claremont National Bank. He was for thirty-four years a warden of Union Church at West Claremont and, in April 1934 was named senior war denemeritus of this church.

Dr Jarvis is survived by his widow Mrs Mabel Jarvis and son, Samuel Gardner Jarvis of Quincy Massachusetts.

THE APPOINTMENT OF DR. MILLER

Dr Ralph E. Miller assistant professor of pathology at the Dartmouth Medical School has been appointed assistant dean of the school and promoted to the rank of associate professor of pathology. He has been granted sabbatical leave for the second semester of the current academic year in order to study pathology under Professor Pick in Berlin—Science 83 228 (Mar 8) 1936.

HOSPITALS

The Woman's Board of the Littleton Hospital aided by the Baldwin Fund, purchased early in December an oxygen tent and a portable x-ray machine complete with a fluoroscope.

NURSES

The quarterly session of the New Hampshire Graduate Nurses Association was held in Manchester December 11 1935. Under the direction of Mrs. Alma VanPelt, Superintendent of Nurses at the Elliot Hospital, Manchester the League of Nursing Education met separately during the morning to consider general business and to listen to a reading of nursing school records.

The principal speaker of the afternoon was Miss Ella E. McNeill of New York City Assistant Director of the National Organization for Public Health Nursing who discussed "Broader Aspects of Community Responsibility for Nursing."

Miss Rose Griffin, President of the Association and Superintendent of the Mary Hitchcock Memorial Hospital in Hanover presided at the afternoon session. The New Hampshire Board members of the organization for Public Health Nursing met with Miss Ruth Whitcomb of Concord.

Dr Warren Butterfield of Concord spoke to the delegates on "The First Aid and Accident Prevention Program of the Red Cross."

The officers of the organization are Miss Rose Griffin President Miss Vernice Patterson 1st Vice-President Miss Alice E. Russ 2nd Vice-President Mrs. Melaine R. Proulx, Secretary and Miss Loretta Landry Treasurer.

The quarterly meeting of the Executive Board of the Keene District Nursing Association was held January 9 1936. The total number of visits during the last quarter was 1,287. Of these there were 598 medical 229 surgical 1.6 obstetrical 164 newly born 120 welfare. The Association has recently purchased an anriscope for the use of the

nurses in examination of babies and young children
The monthly meeting of the Portsmouth Nursing Association was held January 2, 1936 The Association enters upon its thirty first year

CANCER

A series of radio broadcasts, sponsored by the State Cancer Commission, have been given over Station WFEA, Manchester, recently Speakers were Dr James W Jameson, Concord, Dr Deering G Smith, Nashua, Dr Emery M Fitch, Claremont, Dr Harold J Connor, Concord, Dr Clifton S Abbott, Laconia, Dr Howard N Kingsford, Hanover, Dr Walter H Lacey, Keene, and Dr Alfred J Leary, Manchester

PERSONALS

Dr Melba Stewart Perley of Laconia spoke on January 23 to the Mothers' Department of the Lakeport Women's Club She based her remarks upon her experiences at the hospital in the x ray department, illustrating her points with x-ray pictures of children

Dr Ezra A Jones of Manchester was the guest speaker recently of the Laconia Rotary Club and the Keene Rotary Club, speaking of his work among crippled children

Dr Walter H. Lacey of Keene gave an instructive talk on "Carcinoma" before the Keene Fortnightly Club, January 11, 1936

Dr Robert B Kerr of Manchester was elected President of the New England Tuberculosis Association at its meeting at the Hotel Statler, Febru-

ary 7 Dr Kerr is Medical Director of Pembroke Sanatorium and Executive Secretary of the New Hampshire Tuberculosis Association

MEETINGS

Members of the new State Commission for the Study of Occupational Diseases in New Hampshire held their first session on Wednesday, December 12, 1935 at the State House Members of this Committee are Dr Robert J Graves, Concord, Chairman, Eugene J O'Neil, Concord, Secretary, Dr Emery M Fitch, Claremont, Peter Tsiales, Manchester, Daniel Feindel, Berlin, Frederick Graf, Keene, Major A Erland Guyotte, Peterborough, Charles E Greenman, Hampton, and Dr David W Parker, Manchester

The Belknap County Medical Association sponsored a skin clinic on January 17 Dr R E McDonnell of Yale Medical School addressed the clinic in the afternoon, illustrating his talk with slides

The annual meeting of the Hillsborough County Medical Society was held at the Derryfield Club in Manchester on November 15, 1935 The following officers were elected to serve for the year Dr Henry H Dearborn, Milford, President, Dr Charles F Nutter, Nashua, Vice-President, Dr Deering G Smith, Nashua, Secretary-Treasurer Dr Dudley Merrill of Boston spoke on "Dangers Inherent in the Clinical Diagnosis of Cancer"

The Belknap County Medical Society held a meeting at the Laconia Tavern, February 11, 1936 The speakers were Dr Clifton S Abbott, President of the New Hampshire Medical Society, and Dr Carleton R Metcalf, Secretary of the New Hampshire Medical Society The program was in charge of Dr Laura Jacques

VERMONT STATE MEDICAL SOCIETY

THE CAUSES OF SUDDEN BLINDNESS*

BY ARTHUR J BEDELL, M D †

WHEN a patient suddenly goes blind he usually consults his family physician before going to the ophthalmologist

The causes of rapid impairment of sight are numerous Many are easily recognized and often prompt treatment restores function At other times the blindness is part of a constitutional condition for which little or nothing can be done

A differentiation should be made of partial and complete loss of sight To do this best we must adopt a reliable method for determining the degree of visual loss This examination

is divided into two parts, one the central vision and the other the field of vision The general practitioner can very readily and accurately determine the latter by taking the finger field

Acute congestive glaucoma is one of the most frequent, most serious and yet most easily diagnosed causes of sudden blindness The eye condition is so frequently masked by the acute gastrointestinal upset that the picture should be so indelibly impressed upon the minds of all physicians that no case is neglected In glaucoma one or both eyes present an intense cyanotic congestion of the globe and conjunctiva The cornea is hazy, the anterior chamber shallow, the pupil ovoid and dilated with a definite increase in the intraocular tension This last is easily diagnosed by palpation By placing

*Read at the Annual Meeting of the Vermont State Medical Society at Rutland October 18 1935

†Bedell Arthur J—Attending Ophthalmologist St. Peter's and Child's Hospitals and Old Ladies Home Albany N Y For record and address of author see "This Week's Issue" page 653

the index fingers in apposition under the upper margin of the orbit a delicate ballottement indicates the degree of resistance. When the eyeball is hard and it is not possible to dent it, increased intraocular tension is diagnosed. In every case of gastrointestinal upset which occurs in an adult the eyes should be most carefully inspected for if acute congestive glaucoma is overlooked, the patient will eventually become blind, although after a variable time the eyeball whitens, the pupil remains widely dilated and some vision may remain but only for a comparatively short period. The process further continues until finally the eye becomes so painful that enucleation is necessary. As soon as the diagnosis is made the patient should be given a hypodermatic injection of morphin without atropin, eserine 1 per cent solution instilled in the eye, hot compresses applied and arrangements made for an early operation. Delay is dangerous. The operation of choice is an iridectomy and incidentally if you are not doing special work, I urge you to transfer your patient with acute congestive glaucoma to a competent ophthalmologist, not only to protect the patient, but also to save you many regrets for the treatment of glaucoma is an extremely technical one.

Another type of glaucoma comes on so insidiously that there is a steady, imperceptible loss of sight which is frequently not recognized by the patient until there is a very great impairment. In this type the interior of the eye must be examined the field of vision must be frequently charted on the perimeter and the intraocular tension not only measured by gross palpation but also by the exact instrumental means. This form must be treated with the greatest skill sometimes eserine and pilocarpin will retard the process, at other times operations are indicated.

Vascular accidents cause the largest group of cases of rapid failure of sight, and although we may become suspicious of a blood vessel disease, we cannot be certain of the diagnosis until an ophthalmoscopic examination is made. Most of our patients have hypertension but some have low pressure, therefore, the blood pressure reading must not be considered as making the diagnosis but only pointing the way.

Two lesions frequently encountered are sudden closure of the central artery of the retina which may come from an embolus thrombus or endarteritis and the rapid occlusion of the central vein. The fundus picture of the artery obstruction is diagnostic. There is widespread edema. The arteries are either narrow or closed the veins are small and the macular region red. There is very little that can be done for this sudden plugging of an artery. We massage the eyeball, administer vasodilators by mouth or give amyl nitrite by inhalation. Opening the

anterior chamber has been proposed but I have never seen any good result from this dangerous procedure and, therefore, discourage its use. At times there is canalization of the thrombus with some return of vision. Occasionally there is an auxiliary blood vessel system which furnishes blood to the macula and central vision is preserved.

Thrombosis of the central retinal vein may be complete or limited to one branch. Obviously, the amount of visual loss depends upon the extent of the vein disease. In many cases of partial thrombosis the retinal blood flows over the macular region and the patient complains of blindness. There is often a very considerable improvement. In some cases the blood cells fill the filtering angle of the eye and secondary glaucoma develops causing total blindness and often necessitating the removal of the painful globe.

Complete thrombosis of the central retinal vein may or may not be an evidence of a general vascular disease, and a very exhaustive clinical investigation may fail to disclose the reason for the vein occlusion. The blindness is sudden and unaccompanied by any external evidence of disease or by pain. The fundus picture is characteristic the veins are large and distended there is some retinal edema many hemorrhages and frequently white patches. The absorption of the blood and the restoration of circulation does not follow any definite order and subsequent changes are bizarre. Treatment is directed to any discoverable bodily ailment and if the intraocular tension is increased, attempts must be made to control it. Again I repeat that it should be distinctly remembered that both of these serious vascular accidents are found in hypotension as well as hypertension.

Arteriosclerosis of the fundus is so well known and so clearly described by words and photographs that little need be said regarding the various changes which constitute the general picture. A patient with arteriosclerosis may speak of sudden blindness, although in reality the examination will show that he has a full peripheral field of vision and has only lost the central part. This of course means that the patient is unable to read. The disease is usually found in those who are senile, and by senility I do not necessarily mean age. It is caused by an obstruction in the perimacular vessels with a hemorrhage in the choroid cystic degeneration of the macula and the end result is a pale partially depigmented scar. It is usually bilateral although one eye may be involved long before the other. Little or nothing can be done to alleviate the symptoms. The patient is always happier if he understands that he will never become blind as a result of the disease. There is an arteriosclerotic optic atrophy. Fortunately

this is uncommon for it means complete loss of vision in the eye that is involved

When the retina becomes detached from its choroid base there is always a partial loss of visual field. Some detachments are spontaneous and develop without any discoverable reason. On the other hand the retina may be separated as a result of a direct blow upon the eyeball or the stretching of the globe in high degrees of myopia.

An intraocular growth may push the retina forward. Occasionally the separation is caused by nephritis, particularly that which accompanies pregnancy. Examination in the primary type shows that the gray retina moves as the eye changes position. If a choroidal tumor is present the retina may be adherent to the growth or there may be so much fluid surrounding it that at one stage the retina waves as it does in the subretinal fluid detachment. The diagnosis of detachment of the retina is not difficult but the differentiation between the secondary and primary types is sometimes most confusing and the patient must be observed for some time before an accurate diagnosis can be given. We have three diagnostic methods which are of considerable help in such cases. One is the slit-lamp, an intense, brilliant beam of light is thrown into the eye which is then examined with a binocular microscope. Another is serial stereoscopic photographs of the fundus and the third is transillumination. If the detachment is so located that a small lamp can be placed behind it, the light is readily transmitted through a simple detachment, but where there is a tumor the dense growth prevents the light from being seen in the pupil.

The detachments in acute nephritis and in pregnancy are usually so thick that there is little motion of the retina. They are often bilateral and the general condition of the patient is sufficient to guide one to the correct diagnosis. The retina usually becomes spontaneously reattached in these diseases.

Detachment of the retina has for years been looked upon as a hopeless condition and, although patients have been subjected to all sorts of rest and dehydration methods, little success has attended the physician's efforts. But now, thanks to the work of many ophthalmologists scattered over the world, and especially to the late Gonin of Lausanne, Switzerland, operations can be performed upon certain types of detachment. The hole in the retina can be seen and then sealed by means of high frequency or galvanic electricity. This is a technical operation, but the restoration of vision in such a patient gives the ophthalmologist great satisfaction. It is important to remember that if a patient with detachment is to recover his vision by operation, the operation must be performed before the retina has lost its function. When the retina is displaced by a growth, the eye should be

enucleated, for usually the tumor is a sarcoma of the choroid which has a predilection to metastasize in the liver and orbit.

Impure alcohol, wood alcohol and various drugs can cause sudden and complete bilateral blindness which is often ushered in by an acute gastrointestinal upset, sometimes with coma, and unless the eyes are carefully examined the vision may be totally destroyed before the patient becomes conscious. Here again prompt action is imperative. The stomach should be washed out several times a day, saline purgatives administered, lumbar puncture immediately performed and a small dose of salvarsan injected intravenously. If the patient survives, strychnin should be given internally and positive galvanism applied to the eyes. Destructive blindness has been caused by large doses of quinine and more recently by the application of thallium in the form of a depilatory. Since the introduction of dinitrophenol many patients have presented with beginning blindness. In the cases that I have seen the earliest changes have been in the lens, a curious wide spread opacification. Some have progressed to complete cataract, others have remained immature.

Partial blindness follows the prolonged use of tobacco in those who are susceptible to nicotine poisoning. There is a definite loss in the field of vision and the history of tobacco consumption. By the inhibition of tobacco and the use of strychnin, many are cured.

There seems to be decidedly less use of quinine sulphate as an abortifacient. I have seen a patient after the ingestion of a cupful of the drug. The uterus was emptied but the patient remained totally blind, the nerve atrophic and the retinal vessels small.

With the more extensive use of the automobile, and the increased manufacture of storage batteries, lead poisoning is more prevalent than formerly. In some parts of the world, where they still use lead pipes, children are frequently affected, the optic nerves are involved and the sudden blindness almost total. Lead poisoning is often difficult to diagnose. Not only must we have a history of the occupation of the patient but the diagnosis must be confirmed by chemical studies. In the cases that we have seen, the removal of the source of the poisoning, change of occupation, the institution of elimination measures such as the drinking of large quantities of milk, the ingestion of potassium iodid and fresh air have resulted in a favorable outcome.

Sudden blindness may come from an infection of the nasal sinuses. The patient has a head cold and notices that his vision is at first blurred and then becomes suddenly lost.

One of the earliest signs of multiple sclerosis is a rapid loss of sight in one or both eyes. As this disease has periods of remission, a patient

may be treated for a time and as a result of constitutional treatment show a very great improvement but, unfortunately eventually he he comes sightless.

Injury to the head may cause blindness either by a hemorrhage in the optic nerve sheath, a hemorrhage in the orbit, a fracture of the orbit or a severance of the nerve itself. Every case of trauma to the head should be thoroughly examined by a competent ophthalmologist.

Puncture wounds of the eyeball may cause sudden blindness either from infection or primary destruction. Compression of the eyeball may produce a hole in the macula or a rupture of the choroid. These conditions can only be discovered when the ophthalmoscope is correctly used. A severe compression of the chest can result in blindness by extravasation about the optic nerve leading to subsequent atrophy of it. The degenerative changes in the retina, choroid and optic nerve may cause a rapid loss of reading power and the patient speaks of blindness. This defect is partial and can only be diagnosed by the use of the ophthalmoscope.

Tuberculosis syphilis and focal infections cause much blindness. Multiple small thrombotic hemorrhages in the retina may come from the various blood dyscrasias such as leukemia or may be an ordinary allergic reaction. If the hemorrhages do not involve the macula we frequently have restoration of central vision. In

diabetes the patient may have a very great increase in the amount of blood sugar without any change in sight. He may on the other hand have a slight increase above the normal with very intense retinal and choroidal destruction, or only a central scotoma.

In chronic nephritis the patient loses sight as a result of retinal degeneration. The changes in the fundus found in this disease as well as in hypertension, are illustrated by the slides. There may be a marked decrease in sight after exposure to bright light such as in those who have stared at the sun during its period of eclipse, prolonged exposure in the snow and those who use the arc for welding. Blindness may also follow the use of certain drugs like atoxyl and ethylhydrocuprein. Brain tumors may cause partial or complete loss of vision. And finally sudden blindness may be complained of by an hysterical patient at which time the physician must use all of his professional skill and native ingenuity to distinguish between it and some of the obscure brain diseases which it simulates.

Sudden blindness is sufficiently common and its causes sufficiently varied to warrant your attention to the problem so that you may be prepared when the emergency arises. By concerted effort on the part of all of us, much blindness can be prevented and much relieved.*

Illustrated by black and white and colored photograph of the fundus and external conditions.

SYPHILIS IN PREGNANCY

SUMMARY AND CONCLUSIONS*

1 A report is made of the effect of treatment on the outcome of pregnancy in syphilitic women. The data show that congenital syphilis is practically a preventable disease. Its prevention is dependent upon the routine early and repeated use of the serologic blood test on every pregnant woman and upon adequate early treatment once the diagnosis of syphilis has been made.

2 A positive blood reaction during pregnancy is a serious matter to the fetus. Ten times as many syphilitic children were born when the syphilitic mother's blood was positive during pregnancy as when it was negative.

3. The pregnant syphilitic woman was found to tolerate anti-syphilitic treatment as well as or better than the syphilitic woman who had not been pregnant since infection.

4 There is evidence that habitually aborting syphilitic women are capable of producing living apparently nonsyphilitic children when given specific treatment throughout each pregnancy.

5 Many more nonsyphilitic living children were born when anti-syphilitic treatment was begun before the fifth month of pregnancy than when therapy was delayed. This advantage was increased if

the treatment during pregnancy was not only early but adequate that is at least 10 preferably 15 injections of arsphenamine and appropriate heavy metal.

6 If an early syphilis appears late in pregnancy some treatment begun at this period and continued up to termination of pregnancy even though it is only a small amount, will be of value in the production of a living child. To those women with early syphilis who were treated after the fifth month of pregnancy only 7.6 per cent of the children were born dead whereas among a similar group of women with early syphilis to whom no treatment was administered during pregnancy the loss of life was 48 per cent.

7 Treatment during a preceding pregnancy is an efficient protection for the present pregnancy even though the syphilitic woman has a negative blood reaction. It is necessary to treat her throughout each pregnancy to insure a living nonsyphilitic infant.

8 The important factors in controlling clinical progression and relapse in the syphilitic woman are the stage of syphilis on beginning treatment and the amount of therapy administered rather than the pregnancy. The possible exception is the apparent protection pregnancy affords the early syphilitic in avoiding an involvement of the central nervous system.

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 22131

PRESENTATION OF CASE

First Admission A white married unemployed fifty-three year old Syrian male entered complaining of pain over the sternum.

His illness began eleven weeks previously with dyspnea, a sensation of precordial constriction and wheezing respiration. The onset was gradual and these symptoms persisted with varying intensity for about three weeks. During this time he also had knifelike pains in the small of his back and stated that there was swelling of all parts of his body which persisted for about six weeks. This had subsided before admission and his only complaints then were residual weakness and nocturia.

Physical examination showed a well-developed and nourished man in no acute distress. The fundi showed tortuosity of the retinal arterioles. The heart was enlarged and there was a systolic mitral murmur and an accentuated A_2 . The blood pressure was 210/140. The liver edge was just felt.

The temperature, pulse and respirations were normal.

The urine contained a large trace of albumin and an occasional granular cast and red blood cell, but was otherwise negative. Examination of the blood showed a red cell count of 6,300,000, with a hemoglobin of 75 per cent. A phenol-sulphonephthalein test showed 60 per cent excretion and the nonprotein nitrogen of the blood was 36 milligrams per cent. There was a normal urea clearance. A Hinton test was negative.

X-ray studies showed dullness of the right antrum with thickening of the lining membrane. There was also slight clouding of the right ethmoid cells. Measurements of the heart were within normal limits. The apex was blunt-ended and the aorta tortuous.

He was discharged in eleven days.

Second Admission, two years later.

He was followed in the Outpatient Department where his urine was found to show a large trace of albumin persistently and his blood pressure remained elevated at about 220/120. Systolic and diastolic murmurs were audible at the left sternal border. Two months before admission a gradually progressive weakness be-

came so pronounced that he was unable to continue his work. There was occasional swelling of the ankles, dyspnea with very slight exertion, and a nocturia of two to three times. An occasional twinge of pain behind his sternum was readily relieved by nitroglycerine. Three weeks before admission he began to suffer from a "tight pain" behind the middle of the sternum following the slightest effort. Rest, nitrates or a warm local application relieved his distress within five minutes. Two weeks later, following an emotional upset, the pain became much more severe and was not relieved so readily even with continued bedrest. Four days prior to admission the pain became quite intense and persistent. He had a queer tingling sensation in both hands and sweat profusely. The discomfort was at first unaffected by hypodermic medication but later he was able to sleep fitfully. Two days later the pain became unbearably stabbing in character and radiated from the third and fourth interspace at the right parasternal line directly to the back. He coughed up some bloody sputum. There was cyanosis and dyspnea which were relieved somewhat by hypodermic injections and dry cupping. Repeated emesis at the onset of this episode subsided in two days and an annoying cough productive of a small amount of yellow sputum developed and persisted. The cough caused considerable discomfort in a region situated a little above the left nipple.

The past and family histories are non-contributory.

Physical examination showed a well-developed and nourished middle-aged man sitting upright in bed complaining of constant precordial pain. There was flattening of the occiput. The fundi were not examined. There was dullness in the right chest from the sixth rib anteriorly and the eighth posteriorly to the bottom. Tactile fremitus and vocal resonance were increased in this region. Fine râles were audible at both bases and there was a pleural friction rub at the right bottom posteriorly. The heart did not appear to be enlarged. The sounds were regular and of good quality. A_2 was accentuated and greater than P_2 . The blood pressure was 100/85. The abdomen was soft although there was some tenderness in the right upper quadrant. The liver and spleen were not palpated. The remainder of the physical examination was negative.

The temperature was 100.2°, the pulse 100. The respirations were 28.

Examination of the urine showed a specific gravity of 1.010 to 1.018 with a large trace of albumin. The sediment contained an occasional white blood cell and a rare granular cast, but was otherwise negative. The blood showed a red cell count of 4,900,000, with a hemoglobin of 70 per cent. The leukocytes numbered 16,500,

with 80 per cent polymorphonuclears, 2 per cent eosinophils, 2 per cent basophils, and 16 per cent lymphocytes. Blood cultures were negative. The nonprotein nitrogen of the blood was 50 milligrams per cent. The sputum contained pneumococcus, not types I, II or III. An electrocardiogram exhibited a prominent P₁ and P. There was high ST takeoff with a humping of T₁ and a very low T₂. Q R-S₂ was inverted. Lead 4 exhibited an absent Q deflection and ST₄ took off from the descending limb of R, 3 millimeters below the isoelectric level. T₄ was inverted.

The pain and dyspnea persisted with very little change despite the administration of morphin. A pleuropericardial friction rub was reported to be audible over the third right inter-space close to the sternal border. This however, was not confirmed by other examiners. The rales became more pronounced at both bases and pitting edema appeared at the sacrum. On the eighth day the electrocardiogram revealed a slight left axis deviation with a prominent S. ST₁ was convex with a slightly high origin and inversion of T₁. T₂ and T₃ were likewise inverted. Lead 4 exhibited an absent Q, a tall R and a low origin of ST with a diphasic T. Throughout the hospital stay his temperature remained normal, the pulse ranged from 80 to 90 and the respirations were 20. His condition remained essentially unchanged until the fourteenth day when he developed very severe precordial pain and dyspnea while his bed was being made and expired within fifteen minutes.

DIFFERENTIAL DIAGNOSIS

DR. PAUL D. WHITE: "During this time he also had knife-like pains in the small of his back and stated that there was swelling of all parts of his body which persisted for about six weeks." One would like a report of the physical examination at that time. It is evident that we cannot be sure of the diagnosis of this attack without further information. There are a number of things we should think of: congestion or heart failure associated with or due secondarily to luetic aortitis with aortic valvular disease or coronary month involvement, chronic hypertension with a hypertensive heart which had failed at this time, coronary thrombosis with failure ensuing chronic valvular disease, perhaps with aortic stenosis which is often found in middle and in old age at the beginning of heart failure, acute pericarditis with effusion, and even pulmonary embolism, although we would not expect edema with that. Also if the edema was widespread we should have to think of the possibility of nemic involvement.

The edema subsided. We would like to know what treatment he had had during this time because if he had had very little treatment in

the way of digitals and rest we could rule out most of the conditions mentioned above. An acute attack of pericarditis or an acute attack of coronary thrombosis may result in symptoms and signs that will subside spontaneously with out much treatment. You would hardly expect luetic aortitis severe enough to cause failure to subside in this way. Coronary thrombosis is the best bet.

Evidently we have hypertension on recovery from the acute illness and an enlarged heart with a systolic murmur at the apex. What are the causes of such a murmur at the apex? The best and most likely explanation is that the heart is still somewhat dilated and that the murmur is a functional murmur due to enlargement of the left heart. Second in likelihood would be aortic stenosis with the murmur heard best at the apex. A number of times in the past ten years we have been misled by such a murmur, later discovering that the murmur became louder at the aortic valve area. The least likely possibility is mitral disease causing this systolic mitral murmur. The fact that the liver edge was felt is important and favors an acute illness complicating hypertensive heart disease. An acute illness that would explain the precordial constriction followed by this wheezy respiration would be coronary thrombosis, so that the history to this point somewhat favors the combination of hypertensive heart disease with acute coronary occlusion. Hypertensive heart disease itself may be complicated by failure, but we would not expect precordial constriction or pain to be a prominent feature if that were so.

We cannot apparently blame the albuminuria on congestive failure. It does seem as though there must have been some degree of nephritis quite likely secondary to the hypertension.

The Hinton reaction is very important in a middle aged man with heart symptoms. In such a patient we must think of the possibility of luetic aortitis which may show itself by the symptom of oppression under the sternum or by dyspnea. This negative Hinton test is of value; it is against the diagnosis of syphilitic aortitis by about four to one.

The heart was probably slightly enlarged but not dilated at this time, or if it was dilated, not enough so to cause abnormal measurements by x-ray examination but there is a suggestion in the x-ray report that the apex was blunted and the aorta tortuous that would be in keeping with aortic stenosis or with hypertension plus aortic sclerosis.

It would be of interest to know if an electrocardiogram was obtained on the first admission.

"Systolic and diastolic murmurs were audible at the left sternal border." This is the only statement about the diastolic murmur. I would

like to know if the diastolic murmur was heard constantly, and if anybody heard it at the time of the first admission, there is no note later on that it was present or that it was only a temporary finding

All these symptoms can be explained by progressive congestive heart failure

"Three weeks before admission he began to suffer from a 'tight pain' behind the middle of the sternum following the slightest effort" That is angina pectoris certainly. I wonder if at the first illness two years before he might have had the same story. The story, of course, makes one think of acute block of the coronary vessel due to infarction. The prolonged pain was similar in character to the angina pectoris pain.

It hardly seems as if he had congestive failure enough to cause him to raise bloody sputum, but that is a possibility. One should also think of pulmonary infarction with pleurisy complicating the coronary thrombosis as a possible explanation for the pain in the right chest, the cough and the raising of blood. The findings on physical examination support our opinion that there was some involvement of the right lower lobe, probably infarction.

There is no statement of murmurs found in the physical examination at the second admission, we would very much like to know about the aortic diastolic murmur that he had had.

"The blood pressure was 100/85." That is a striking drop in blood pressure and would be consistent with coronary thrombosis or with any other condition in which there was an acute heart or circulatory failure.

There is some importance in the statement that the spleen was not palpated. No note is made of the clubbing of the fingers. Later on blood cultures were taken. Apparently there was a thought of bacterial endocarditis.

The classical leads of the electrocardiogram were not very striking at first although there was stated to be a high origin of T_1 , low T_2 and rather low origin of T in lead 3. From lead 4, the precordial lead, however, we received much more help. The so-called Q wave which ordinarily is well marked was absent, so far as we know that is fair evidence of an established infarct, not necessarily an acute infarct, in the left ventricle. Also the T arose from the descending limb of the R wave, very low down. This change was probably associated with the acute illness.

"A pleuropericardial friction rub was reported to be audible over the third right interspace close to the sternal border." That was due to pleurisy associated with the pulmonary infarct or to pericarditis secondary to the coronary thrombosis if such was present.

In the second electrocardiogram the three classical leads present much more evidence than we had before of what seems to be an acute process. The T wave in lead 1 has become in-

verted, which is an important change, and the T in lead 2 has become inverted, which is also important. Thus, T_1 and T_2 are now definitely inverted, while in lead 4 the Q is still absent and the T rises farther up on the descending limb of the R.

We cannot diagnose with certainty secondary coronary occlusion, or rupture, or angina pectoris, the last-mentioned possibility is least likely because he lived fifteen minutes after the pain began. There are many remote possibilities as to the exact cause of death.

I believe that the diagnosis here is hypertensive coronary heart disease with an old myocardial infarct and probably a fresh one, a complicating pulmonary infarction, and congestive failure, the heart being unable to stand the extra strain. I do not think that luetic aortitis is present, it cannot explain the whole picture, particularly the electrocardiogram, as it is given. We have no proof of valvular disease. Aortic stenosis and regurgitation would have to be thought of and possibly careful repeated examinations might have confirmed those murmurs heard at first, but the chances are against such a diagnosis. From the evidence we can have a hypertensive complication of aortic stenosis, but that is not likely either. Remote possibilities of dissecting aneurysm, bacterial endocarditis, and such a rarity as dissection of the coronary artery, I think we can rule out.

DR. GERALD BLAKE. This patient's symptoms of angina recurred about three weeks before his second admission and then only following exertion. Four days before admission he had what we thought was coronary occlusion and he came in with the picture of coronary occlusion with signs of myocardial failure. He described his pain as burning during the first day or two, "pain like fire", and, following that, as a stabbing pain at the root of the sternum, going through to the back. The signs in the lungs were as described and could be explained as chronic passive congestion, with probably an infarction on the right. His final attack was accompanied by a slight increase in dyspnea, slight increase in cyanosis and slightly more rapid breathing, and we thought that that was probably due to occlusion of the main left coronary vessel rather than to a rupture of the myocardium.

DR. HOWARD SPRAGUE. I saw the patient once in consultation on the ward. I agreed at that time that the diagnosis was the one that Dr. White has outlined. I did hear at that time what seemed to be a pericardial friction rub. The electrocardiogram certainly suggests the apical type of coronary occlusion.

CLINICAL DIAGNOSES

Coronary thrombosis
Generalized arteriosclerosis

Chronic vascular nephritis.
Pulmonary infarct.

DR. PAUL D WHITE'S DIAGNOSES

Hypertensive, coronary heart disease
Coronary thrombosis (anterior descending branch of the left coronary artery)
Infarcts of apex of left ventricle, old and new
Pulmonary infarct.
Congestive failure
Angina pectoris (history)

ANATOMIC DIAGNOSES

Coronary thrombosis, right descending branch
Myocardial infarction
Pericarditis, acute fibrinous.
Mural thrombi left ventricle
Pulmonary edema, bilateral
Hydrothorax, right.
Pulmonary atelectasis, right.
Arteriosclerosis Coronary and cerebral marked, aortic, moderate.
Perihepatitis
Perisplenitis.
Chronic vascular nephritis
Oxycephaly
Obesity
Parathyroid hyperplasia, slight

PATHOLOGIC DISCUSSION

DR. TRACY B MALLORY The autopsy showed a large area of infarction in the heart at the apex of the left ventricle involving nearly two-thirds of the interventricular septum. The area of infarction was soft, the muscle entirely different in color from the remainder of the myocardium. It was evident that it had been present long enough to get a considerable degree of reaction but not long enough for complete scarring. From the myocardial infarct itself we were not able to make out any clear evidence of successive infarctions, though the degree of muscle cell degeneration varied slightly from place to place. There were, however, two quite separate thrombi overlying the infarct on the endocardium of the left ventricle. These were evidently of different age, one was firmly and almost completely organized the other showed only the very slightest trace of organization so I feel pretty sure we are dealing with two successive infarcts occupying almost exactly the same spot in the myocardium. The coronary that was involved was the descending branch of the right. Particularly enough, the left showed marked sclerosis but was not occluded.

DR. WHITE The area involved was the apex of the left ventricle?

DR. MALLORY Yes. One feature that impressed me particularly at the autopsy was the extent of the pericarditis. The entire pericardial cavity was involved in a very severe

fibrinous pericarditis showing early signs of organization.

DR. WHITE I meant to have said that a pericarditis could account for some modification of the electrocardiogram but not to the extent found here.

DR. MALLORY The average case of coronary thrombosis will almost invariably show localized pericarditis over the area of infarction but diffuse pericarditis such as this is really quite unusual and I think it might explain the very marked radiation of pain through to the back.

A PHYSICIAN Was the pleura involved too?

DR. MALLORY The right pleural cavity contained about half a liter of pleural effusion and there was collapse of the lower lobe on the right, no pulmonary emboli, no infarcts.

The other organs showed grossly only marked arteriosclerosis, particularly of the abdominal aorta and of the vessels of the circle of Willis. Microscopically there is an early arteriosclerosis such as one would expect in hypertension showing up most markedly in the kidneys.

DR. WHITE May I add one note about the electrocardiogram evidence? The classical leads, that is, leads 1, 2, and 3, were not wholly convincing in the first record but the fourth or chest (precordial) lead gave a great deal of help through the absence of the so-called Q wave. This is an illustration of the occasional value of the routine chest lead.

CASE 22132

PRESENTATION OF CASE

A thirty six year old white Portuguese rayon mill worker was admitted complaining of epigastric discomfort and loss of weight.

About a year and a half prior to entry several hours after his evening meal the patient felt dizzy and shortly afterward had a desire to defecate. He passed a very black stool and fainted. Upon recovering consciousness after four or five minutes he found himself lying in a pool of dark blood which he believed he had vomited. He was sent to a hospital where x ray studies were said to be negative. A Sippy diet was instituted and the patient was discharged much improved after three to four weeks. He felt well for about six months, whereupon he observed some pallor, weakness, and slight dyspnea with exertion. Suddenly one evening he had a sensation of fullness in the chest and expectorated a cupful of dark blood which was streaked with red. For two succeeding days there again were tarry stools. The Sippy régime was reinstituted and he continued well except for a sensation of epigastric fullness which occurred after meals. This was relieved by emetation. About ten months before admission he began to have a tight gripping sensa-

tion in the midepigastrium. This usually occurred immediately after breakfast and persisted throughout the day with an exacerbation of intensity following each meal. Relief was spontaneous after rest at night but medication had no effect. A milk and cream diet resulted in relief from this symptom after about two months. At this time a new symptom manifested itself: all ingested food appeared to stop momentarily behind the xiphoid, cause a slight pain and a feeling of fullness, pass with a rather sharp pain, and leave a residuum of burning pain for about ten to fifteen minutes. Dry solid food, such as toast, caused the discomfort to persist for the entire day. Another x-ray at this time was negative. During the succeeding months he became progressively weaker, short of breath, and his weight decreased from about 130 pounds to 105 pounds. There were no further fatty stools. He continued to work up to three weeks before his entrance to this hospital. The skin of his face and forearms had become slightly browned during the last two years. This he attributed to the action of sulphuric acid fumes with which he had considerable contact.

Physical examination showed a poorly nourished white male in no acute distress. An acneiform eruption was noted over the upper arms and back. The mouth exhibited extensive pyorrhea with brownish-blue pigmentation of the upper and lower gums. The pharynx was injected and there were three small hemorrhagic spots upon the mucosa of the hard palate. The lungs were clear and the heart normal. The blood pressure was 94/78. The liver extended four fingerbreadths beneath the costal margin. It was not tender but felt hard and nodular. Rectal examination elicited only a single small thrombosed hemorrhoid.

The temperature, pulse, and respirations were normal.

Examination of the urine was negative. The blood showed a red cell count of 5,080,000, with a hemoglobin of 90 per cent. The white cell count was 10,000, 69 per cent polymorphonuclears. A Hinton test was negative.

A gastrointestinal series showed a circular mass lying on the left side of the lower end of the esophagus forming a lobulated margin. There was rigidity of the upper third of the lesser curvature including the fundus with bulging in this region. The entire stomach was slightly displaced to the left and there were pressure defects in the lower end of the antrum, on the cap and the upper flexure of the duodenum.

One week after entry the patient suddenly complained of severe upper abdominal pain which was most severe on the left side. The pain rapidly became generalized and the abdomen became rigid, tender, and a tympanic note was obtained by percussion over the liver area.

An x-ray of the abdomen showed free air beneath both leaves of the diaphragm. A laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR ARTHUR W ALLEN: Will you demonstrate the x-rays, Dr Schatzki?

DR RICHARD SCHATZKI: Here is the area where a temporary stop in the barium column was described about two inches above the diaphragm. This is the outline of the esophagus, the left margin is irregular, whereas the right side is fairly regular. This irregularity continues down to here, involving the upper third of the stomach. This region was rigid. There was displacement of the stomach to the left. It was very difficult to fill the cap and second portion of the duodenum, apparently due to pressure from outside. On this spot film the defect in the lower end of the esophagus is better demonstrated.

DR ALLEN: This case is that of a young man whose first symptom is that of severe gastrointestinal hemorrhage. The fact that he had no great pain at the time of the onset of the hemorrhage would not be particularly noticeable if you were going to try to explain the severe bleeding from the most common cause, that is, duodenal ulcer. A certain number of duodenal ulcer patients do not have any pain before they have a rather severe hemorrhage. The fact that his x-rays were negative after this massive hemorrhage would not necessarily rule out a bleeding duodenal ulcer as a cause, because these are usually on the posterior wall of the duodenum and it takes a rather special technique to demonstrate a lesion in this region. Or if the lesion which caused his hemorrhage was at the cardia or high on the lesser curvature of the stomach, near the esophagus, the x-ray examination might be negative. It is, I believe, a difficult place to show by some of the ordinary routine gastrointestinal methods.

The fact that the Sippy diet relieved him of his difficulty for a while is not particularly significant because if he had a lesion in his lesser curvature or in the duodenum I think he might have been relieved by such a diet, any bland diet would have helped him temporarily, particularly with the rest that went with it. The new symptom of discomfort after he ingested food, which developed about eight months prior to admission, is strongly suggestive of some actual narrowing of the opening of the esophagus into the stomach.

He comes in with loss of weight, with a brown skin. One wonders how much you can tell about the color of the skin in a man of this nationality because a great many Portuguese are dark. I am sure I have no idea what possible bearing the sulphuric acid fumes could have on this case. He does have very low blood pressure of

94/78 which with his brown pigmented skin might suggest Addison's disease or something of that nature, but I believe in emaciated patients, particularly with malignancy we also see, in the terminal stages, a type of skin with lowered blood pressure, and so forth, that is not unlike this.

The fact that his red blood cell count was normal is a little disturbing. One would expect a man with this amount of loss of weight with the amount of difficulty he had had ingesting proper food and with a lesion that is as large as this involving the lower end of the esophagus and stomach, to show a certain amount of anemia. It is a little confusing that we have such a perfect blood picture.

Now as to the various causes of severe gastrointestinal hemorrhage, the commonest is duodenal ulcer and after that I presume we must put gastric ulcer, then an esophageal varix, then polyp of the stomach, and lastly carcinoma. These are the things that can and do commonly account for massive hemorrhage from the upper gastrointestinal tract. Now can this man have had a bleeding duodenal ulcer in the beginning and an associated lesion high in the stomach or lower end of the esophagus, and could hemorrhage come from the duodenal ulcer and his symptoms be relieved by Sippy diet? We do not get any help from the type of bleeding which he had as to where it came from particularly, because in the duodenal ulcer cases about one third vomit the blood, about one-third pass it entirely by rectum and the other third pass the blood in both directions, which is what this man did.

The final admission with exitus occurring as it did would mean he had a perforation of a hollow viscus, most likely his stomach or the lower end of the esophagus, producing gas under the diaphragm. With the history as it is given there can be no doubt but that he had a perforated hollow viscus and it is most likely in this neighborhood. Operation was performed which I would anticipate as being unsuccessful, because if a lesion of this size and character perforates one could never hope to close such a perforation surgically. Perforation of a malignant lesion of a hollow viscus is usually fatal. It almost invariably is fatal regardless of what portion of the gastrointestinal tract it involves. It is not always fatal in the colon but it is very apt to be.

I should suppose that we would have to be prepared to find that this man had an old scar in the duodenum which might have accounted for his first hemorrhage. On the other hand I am inclined to try to explain it all on the basis of this lesion at the lower end of the esophagus and the upper end of the stomach and I believe that he had a malignant lesion

here possibly developing upon ulcer which finally perforated, causing his death.

Dr. Rackemann has called my attention to the big liver. I should have mentioned that I suppose a large, hard, nontender, nodular liver is perfectly consistent with a malignant growth of this size and we might expect to find that the liver was full of metastatic cancer.

CLINICAL DIAGNOSES

Carcinoma of the stomach with metastases
Bronchopneumonia
Perforation of the stomach.

DR. ARTHUR W. ALLEN'S DIAGNOSES

Carcinoma of the lesser curvature of the stomach and the lower end of the esophagus.
Perforation of the malignant growth
Metastasis to the liver
Peritonitis

ANATOMICAL DIAGNOSES

Carcinoma of the stomach with perforation and metastases to the liver, regional lymph nodes and pelvis
Bronchopneumonia, bilateral.
Pulmonary edema and congestion, bilateral
Pleuritis, chronic fibrous, bilateral acute fibrous, left.
Hydrothorax, left, slight.
Peritonitis, acute fibrinopurulent, and chronic fibrous
Subphrenic abscess, left.
Perisplenitis.
Arteriosclerosis, slight.
Emaciation, marked

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. The autopsy showed a carcinoma which involved the last two and a half centimeters of the esophagus and the upper three and a half centimeters of the stomach. Whether it was primary in the base of the esophagus or in the cardia of the stomach is pretty difficult to say. I, personally, am inclined to think it was primary in the stomach. It had perforated of course. We found the perforation on the anterior surface of the stomach close to the cardiac orifice but only with some difficulty since it proved to be not much over a millimeter in diameter.

The case interested us a good deal from the character of the metastases. You will remember that a few months ago we presented a case of cancer of the esophagus in which nodules of metastatic cancer ran upward from the primary growth, a considerable distance up the esophagus, so that an x-ray characteristic of esophageal varices was produced. This man showed the same thing to a somewhat less degree.

There was a whole string of submucosal nodules running up the esophagus. Another point of some interest was that the metastases to the liver were all of them in the left lobe. The liver was adherent to the growth and it is possible that it was involved by direct extension. The other possibility is that it is to be explained on Graham's theory, that blood from certain parts of the portal system tends regularly to go to the left lobe while that from other areas goes to the right lobe. The caudal of the stomach would be in the area which tended to drain into the left lobe.

There was a well-marked subdiaphragmatic abscess on the left, a little reactive irritative

pleuritis in the right pleural cavity and a terminal bilateral pneumonia.

A PHYSICIAN: Was there any effusion in the chest?

DR MALLORY: A few cubic centimeters of turbid fluid.

A PHYSICIAN: Was there anything in the adrenals?

DR MALLORY: No.

A PHYSICIAN: Was the perforation successfully closed at operation?

DR MALLORY: No.

A PHYSICIAN: And you found the diaphragm normal?

DR MALLORY: Yes.

JOHN SCOTT HALDANE

THE death of John Scott Haldane on March 15, 1936, removes a great international figure in physiology and scientific medicine—a personal life as remarkable in some respects as Professor Pavlov whose death was announced three weeks ago in these columns. J. S. Haldane came of the Haldanes of Glencragles, a family long distinguished for its brilliant intellectual attainments. His father Robert Haldane, was a well known Scottish barrister (writer to the Signet) his mother Mary Burdon Sanderson was a sister of John Burdon Sanderson the first incumbent of the chair of physiology at Oxford. His sister Elizabeth Sanderson Haldane, a woman of high attainment in philosophy and letters, is a foremost authority on Descartes, his brother Viscount Haldane (Richard Burton Haldane, 1856-1928) was the well known British statesman and War Minister, and finally his son Professor J. B. S. Haldane and daughter Naomi Mitchison also exemplify the versatility and remarkable talent of their line.

After his preliminary education at the Edinburgh Academy, J. S. Haldane went to Oxford where he received training in physiology under his uncle Burdon Sanderson, after a short period in London, during which time he received his medical qualifications, he returned to Oxford as Demonstrator in Physiology (being later appointed Reader), and he remained at Oxford until the end of his life. The facilities of the Oxford Laboratory were so meager that Haldane erected a private laboratory in his house, and during the last twenty five years most of his investigations were carried out under his own roof, and unfortunately students seldom had contact with him.

Haldane will always be remembered for his pioneer studies upon the physiology of respiration, he introduced a simple method for analyzing the constituents of expired air, his apparatus for gas analysis now being found in every physiological laboratory in the world. Haldane's most celebrated paper was published with J. G. Priestley in 1905. It bore the title "Regulation of the lung ventilation" (*Journal of Physiology*, 32, 225-266, 1905). In an ingenious series of experiments carried out upon themselves they proved that

'The respiration centre is exquisitely sensitive to any rise in alveolar CO₂ pressure, a rise of 0.2 per cent of an atmosphere in the alveolar CO₂ pressure being for instance sufficient to double the amount of alveolar ventilation during rest (See table)

"When the oxygen pressure in the expired air falls below about 13 per cent of an atmosphere, the respiratory centre begins to be excited by want of oxygen and the alveolar CO₂ pressure begins to fall.'

Thus is a classical study in the history of physiology, a landmark not only in the field of respiration but in the larger field of clinical science since it illustrated in a beautiful manner how well-controlled physiological studies might be carried out on human beings. Haldane's abiding interest in respiration continued until the end of his life. His Silliman Lectures given at Yale in 1916 culminated in a monograph bearing the title *Respiration*, originally published by the Yale Press in 1922 and just reprinted after complete revision with J. G. Priestley in 1935. It would be impossible to comment fully on the importance of this book, many felt that it had rather glaring shortcomings, which arose out of Haldane's philosophical turn of mind. In the first edition the chapter on oxygen secretion by the lungs caused some who had done far less work than Haldane to shrug their shoulders and while there is room for disagreement concerning this phase of Haldane's work there are few scientific expositions which have so sharpened the critical faculties of students and

the book itself remains as the only comprehensive monograph in English on the physiology of respiration

Haldane and Priestley's original table showing the relation between CO₂ tension in alveolar air and lung ventilation

Haldane rendered great service to his country and to applied physiology generally through his studies of respiratory hazards e.g., in mines, tunnels, caissons, and various other conditions of altered atmospheric pressure or contamination of the atmospheric air. The distinguished work of Henderson and Haggard in this country was largely influenced by Haldane's pioneer studies as was that of many physiologists on the continent.

Philosophically Haldane has generally been referred to as a vitalist. He was exceedingly impatient with the naive postulates of behaviorism, tenaciously maintaining that living matter could never be accounted for by physics and chemistry alone. His many efforts to harmonize philosophy, science and religion will be found in *Essays and philosophical criticisms*, 1883, *Mechanism of life and personality*, 1913, *Organism and environment*, 1917, *The New physiology*, 1919, *The sciences and philosophy* (Gifford Lectures), 1929, *The philosophical basis of biology*, 1931, *Materialism*, 1932, *The philosophy of a biologist*, 1935.

Personally Haldane was a man of unusual charm. For some years he had become progressively stooped and had to cock his head in a curious manner in order to make his face visible to an audience, but when his eye caught yours it seemed to penetrate your soul. In manner he was detached and, as with Burdon Sanderson, the stories are legion of his absent-minded ways. Students of Oxford saw him more frequently catching a train a second or two before it was due to depart than they did in his laboratory, but those who were privileged to see him in his house found him a gracious and most fascinating host.

“THE OLD DOCTOR’S ALMANAC”

CLIMATOLOGY has long been suspected of having its alliance with medicine, and climate its influence upon disease, rickets is less florid in the sunny South than in our fog-bound northern climes, and is practically unknown among the rank verdure of the tropics, rheumatic fever hides its face in sunny latitudes and sufferers from asthma find relief in the dry highlands of Arizona.

It has remained for an Austrian physician, however—a member of the Vienna Board of Health, according to our esteemed contemporary, the *New York Times*—to elaborate a calendar of diseases corresponding to the alternations of climate with variations of temperature, humidity and barometric pressure. This Almanack, recently published, represents a labor of eight years and a study of some 20,000 cases.

According to this calendar, “January is the month of measles, February brings snowdrops and hay fever, March is the month of pneumonia, the appearance of the lily of the valley in May corresponds with the increase in asthma and appendicitis.

“June roses herald the troubles connected with the gallbladder and liver, July increases the sufferers from heart trouble, August is the month of unclassified malaises, September sees the beginning of the ‘cold in the head’ season, which reaches its height in November.

“December is the month of digestive troubles, which are largely caused by the lack of fresh vegetables.”

Perhaps with this almanac, synoptically printed, a vade mecum may be available which will do away with many a bulky textbook of disease, and a new era of more precise diagnosis will be inaugurated. Who knows but that, given a few years of trial—and years are fleeting—and the sling psychrometer and the aneroid barometer will replace the stethoscope and the sphygmomanometer, and the relief of abdominal distention will be measured in terms of wind velocity?

DYSMENORRHEA

There are two types of dysmenorrhea, primary and secondary. Primary dysmenorrhea is uncomplicated by any pelvic pathology capable of causing uterine pain. Secondary dysmenorrhea is due to accompanying inflammations, tumors, etc. It is with primary dysmenorrhea that we are concerned. The symptoms and diagnosis need no elaboration, for the term itself is sufficiently descriptive.

The treatment of primary dysmenorrhea is difficult and often disappointing but if general rules of procedure are laid down and followed, the patient will obtain relief in the end. The outline should proceed from the simplest method to the most difficult or serious. All possibilities of a psychic cause for dysmenorrhea must be ruled out before any other treatment is instituted. The anxious mother or older sister should be eliminated.

Psychiatric treatment is successful infrequently but it must be tried if there is any suspicion, for other methods will fail if the main cause is psychogenic.

Primary dysmenorrhea may in some instances be assumed to be of endocrine etiology and if this is true some hormone should be of aid in the treatment. Many patients with dysmenorrhea have an accompanying underdevelopment of the uterus and to develop such a uterus should be the aim of the physician. In experimental animals and in some instances in human beings the use of estrogenic substances has proved successful in enlarging the underdeveloped uterus. The use of estrin is therefore justifiable. It is also true that estrin causes a marked sensitization of the uterine smooth musculature to the posterior pituitary hormone pituitrin (oxytocic principle). The corpus luteum hormone progesterin is known to neutralize estrin and thus desensitize or prevent the sensitization of the uterine musculature. Progesterin can therefore be used with some hope of success in patients with an oversensitive uterine

A series of short selected articles by members of the Section is being published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the Section.

musculature Urinary prolactin (luteinizing factor) or pituitary prolactin (luteinizing factor) can be utilized in the same way. The hormone should cause luteinization of the follicles and thus the patient's own progesterin will neutralize the sensitizing estrin. It is known that estrin will inhibit the pituitary from secreting prolactin. If therefore there is an excess of estrin estrin can be given the patient with the hope of preventing further secretion of prolactin and therefore less secretion of the patient's own estrin. The estrin should be omitted a few days before the onset of the menstrual period and it is assumed that in the time left between omitting estrin and menstruation the patient's prolactin will not have had time to cause enough estrin secretion to sensitize the uterine musculature. The above are the theories for the use of hormones in dysmenorrhea.

If endocrine methods of attack fail, the simplest surgical procedures should be tried. Sometimes it is noticed that, after taking an endometrial biopsy in the office, the next menstrual period is less painful. In taking an endometrial biopsy there may be a slight stretching of the internal os and it can be assumed that this procedure relieved the pain. It seems logical then to try further dilatation in the office. By infiltrating the os with novocain or using cotton pledgets of local anesthetics (nupercaine, pontocaine) in the os or by using evipal in small doses moderate dilatation can be done without much discomfort. If the dilator is well lubricated it is surprising how easily a fairly satisfactory dilatation can be accomplished.

When this type of treatment has proved unsatisfactory the external os should be thoroughly dilated under an anesthetic. This dilatation should be careful, slow, and very thorough. It is not sufficient simply to pass the dilators, but a real dilatation must be kept up for at least fifteen minutes. Often when doing the rectal examination a widening of the uterocervical segment is noted. This thickening is similar to the hard area noted about the pylorus in pyloric obstruction in children. It is sometimes difficult properly to dilate this area and it is safe and proper to section it. With a finger in the rectum and a long pointed knife this area can be cut through longitudinally and a piece of gauze packed in the split area to keep it open. After regular dilatation and dilatation with incision the internal os should be kept open by dilatation with a lubricated dilator in the office. This method insures a longer and more satisfactory result from surgical dilatation.

Some dysmenorrheas cannot be relieved by these methods and if, in a virgin, a retroflexion is found or if in a multipara a large boggy retroverted uterus is found, suspension of such a uterus combined with dilatation of the internal

os is justifiable. Suspension of the retroverted vaginal uterus or of the anteverted vaginal uterus is not so frequently followed by relief of pain.

Lately presacral or superior hypogastric neurectomy for relief of pain has been advocated. Without doubt this method of treatment is eminently satisfactory. If at any abdominal operation sufficient reason for the dysmenorrhea is not found it should be performed. No ill effects to the bladder, bowel, libido, or pregnancies have been reported. It will not cure all patients. In some the pain which seems organic will be found to be psychogenic and no relief obtained from the operation. In others aberrant nerves or lack of sufficient radical excision of the nerves will not relieve the pain as expected. It is not a 100 per cent cure but is successful in about 80-90 per cent of cases.

Last of all if the pain is intractable and no method can relieve it hysterectomy is justifiable. This is especially true in older women who have had children and in older virgins who understand what hysterectomy means to them. In youth it should never be necessary and should be reserved for later life.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning March 29

Berkshire

Thursday, April 2, at 4 30 P M, at the House of Mercy Hospital, Pittsfield. Subject: Dermatology—Ten Common Skin Diseases—Diagnosis and Treatment, (1) Impetigo Contagiosa, (2) Scabies, (3) Acne Vulgaris, (4) Psoriasis and Seborrheic Dermatitis, (5) Epidermophytosis, (6) Herpes Simplex and Zoster, (7) Eczema, (8) Erythema Multiforme, (9) Verruca Vulgaris and (10) Dermatitis Medicamentosa and Dermatitis Venenata. Instructor J H. Swartz. Melvin H. Walker, Jr., Chairman.

Bristol North

Wednesday, April 1, at 7 30 P M, at the Morton Hospital, Taunton. Subject: Kidney and Bladder Diseases A and B (Medical)—Acute and Chronic Nephritis. Instructor E M. Chapman. Arthur R. Crandell, Chairman.

Bristol South (New Bedford Section)

Friday, April 3, at 4 00 P M, at the St. Luke's Hospital, New Bedford. Subject: Kidney and Bladder Diseases A and B (Surgical)—Hematuria, Its Significance in Surgical Diseases of Kidney and Bladder. Prostatism and Related Diseases. Cystitis and Pyelitis. Instructor G G. Smith. Harold E. Perry, Chairman.

Norfolk*

Friday April 3 at 8 30 P M at the Norwood Hospital, Norwood Subject Arthritis—
(a) Medical Care of Patient in the Home
(h) Orthopedic Treatment in Hospital and Aids in Home Treatment Instructors A. A. Horner and J S Barr H. B C Klemer Chairman.

Worcester (Milford Section)

Wednesday April 1 nt 8 30 P M at the Milford Hospital, Milford Subject Kidney and Bladder Diseases A (Medical)—Acute Nephritis — Etiology Diagnosis and Treatment. Nephrosis and Its Treatment In instructor L. B Ellis. Joseph I. Ashklus, Sub-Chairman

The Course previously given at the Faulkner Hospital will be combined with the group at the Norwood Hospital

MASSACHUSETTS LEGISLATIVE
NOTES

Senate 321 which provides for an investigation of the desirability of the creation of a State Hospital for the treatment of infantile paralysis and arthritis has been favorably reported in the House

Senate 51 which was designed to provide a division of the North Reading State Sanatorium for the treatment of cancer cases has been given leave to withdraw

House 35 designed to provide for the annual registration of physicians has been referred to the next annual session.

House 949 designed to abolish compulsory vaccination has been given leave to withdraw

MISCELLANY

THE APPOINTMENT OF DR. HANS ZINSSER

Dr Hans Zinsser professor of bacteriology and immunology at the Harvard Medical School since 1923 has been appointed Charles Wilder professor of bacteriology and immunology He succeeds Professor Milton J Rosenau—*Science* Vol. 83 No 2151

THE MASSACHUSETTS CENTRAL HEALTH
COUNCIL

With no paid officers or executive the Massachusetts Central Health Council has recently held an election and has appointed a legislative committee This Council has worked to aid the passage of the medical education bill of this session and had much to do previously with the successful launching of the present Massachusetts State Health Commission, now engaged through its fourteen committees in a study of the health needs and laws of the Commonwealth After the forthcoming report of this Commission in 1936 the Council hopes that its constituent health agencies will render important service in promoting indicated changes in health work procedure and to win legislation.

The elected officers are Miss Sophie C Nelson of

the John Hancock Mutual Life Insurance Company President Dr Gaylord W Anderson of the State Department of Public Health Vice-President, and Arthur J Strawson, of the Massachusetts Tuberculosis League Secretary Treasurer

The constituent agencies of the Council each represented by two administrative board members, are as follows Dental Hygiene Council of Massachusetts Massachusetts Public Health Association Massachusetts Organization for Public Health Nursing Massachusetts Department of Public Health Massachusetts Medical Society Massachusetts Department of Labor and Industries Massachusetts Society for Mental Hygiene, Massachusetts Society for the Control of Cancer Massachusetts State Nurses Association Massachusetts Tuberculosis League Massachusetts Veterinary Association Massachusetts Society for Social Hygiene New England Heart Association, Metropolitan Chapter of the American Red Cross New England District of the American Association of Hospital Social Workers and New England Health Education Association.

DR. H. W. SCHOENING NEW ASSISTANT CHIEF
OF BUREAU OF ANIMAL INDUSTRY

Appointment of Dr Harry W Schoening, chief of the Pathological Division of the Bureau of Animal Industry as an assistant chief of the Bureau is announced by the U S Department of Agriculture Dr Schoening will continue as chief of the Pathological Division, but will devote time also to administrative duties dealing with general Bureau research in livestock diseases

He was named chief of the Pathological Division in 1933 to fill the vacancy created by the death of his predecessor Dr J S Buckley

Dr Schoening is a native of Philadelphia Pa. and holds a commission as a major in the Reserve Corps of the Army Veterinary Corps He was a second Lieutenant of the Army Veterinary Corps in 1918. He also is a member of the American Veterinary Medical Association the Society of American Bacteriologists the National Association of the Bureau of Animal Industry Veterinarians and the Academy of Science

SMOOTH OLIVE OIL RACKETEERS FOILED
BY FEDERAL FOOD MEN

It was a good racket while it lasted—the olive oil" racket with cheap tea seed oil substituted for the more expensive olive oil. But a Federal chemist has at last found a way to identify the tea seed oil, and the Food and Drug Administration has started legal action to confiscate thousands of gallons of the adulterated oil. The salad oil racketeers will now have to shandon ten seed oil as a source of illegitimate profits just as in the past they have had to abandon cottonseed oil peanut oil, sesame oil sunflower seed oil and others as adulterants of olive oil.

It is a long story with the racketeers shifting

from one cheat to another trying to keep ahead of the Government and the Government chemists working in their laboratories to devise methods of exposing the cheats, methods so conclusive that they would stand up in court and cause conviction of the cheaters. Time and again the laboratory men have caught up and the test tube has exposed one variety of adulteration, forcing the racketeers to a new dodge—*Bulletin, U S Department of Agriculture*

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR FEBRUARY, 1936

	Feb, 1936	Feb, 1935	5 Yr Average*
Anterior poliomyelitis.....	2	2	2
Chickenpox	1220	1202	1135
Diphtheria	32	39	116
Dog bite	503	506	288
Epidemic cerebrospinal meningitis	23	2	5
German measles.....	424	1908	461
Gonorrhea	396	360	442
Lobar pneumonia	799	475	547
Measles	2477	2097	3095
Mumps	2213	290	638
Scarlet fever	1095	723	1354
Syphilis	426	379	339
Tuberculosis, pulmonary.....	214	316	279
Tuberculosis, other forms.....	28	38	34
Typhoid fever	9	1	8
Undulant fever	4	3	
Whooping cough	310	817	852

*Based on the figures for the preceding 5 years

RARE DISEASES

Actinomyces was reported from Boston, 1

Anterior poliomyelitis was reported from Lowell, 1, Malden, 1, total, 2

Anthrax was reported from Peabody, 1, Pittsfield, 1, total, 2

Diphtheria was reported from Athol, 1, Boston, 12, Dracut, 1, Fall River, 3, Haverhill, 2, Lowell, 5, Malden, 1, Melrose, 1, North Attleboro, 1, Revere, 1, Somerville, 1, Tewksbury, 2, Worcester, 1, total, 32

Encephalitis lethargica was reported from Townsend, 1

Epidemic cerebrospinal meningitis was reported from Boston, 14, Lynn, 1, Newburyport, 1, Newton, 2, Rockland, 1, Spencer, 1, Webster, 1, Winchester, 1, Worcester, 1, total, 23

Pellagra was reported from Nahant, 1, North Adams, 1, total, 2

Septic sore throat was reported from Beverly, 1, Billerica, 1, Boston, 5, Chicopee, 1, Easton, 1, Fitchburg, 1, Gardner, 2, Haverhill, 1, Marshfield, 1, Milton, 1, Newton, 1, Stoneham, 1, total, 17

Trachoma was reported from Worcester, 2

Trichinosis was reported from Agawam, 1, Cambridge, 1, total, 2

Typhus fever was reported from Boston, 2, Peterham, 1, total, 3

Undulant fever was reported from Beverly, 1, Norfolk, 1, Sheffield, 1, Weston, 1, total, 4.

Diphtheria was reported to a lower figure than for February, 1935, after a poor start in January due to a local outbreak

Although most of the increase in reported epidemic cerebrospinal meningitis is due to outbreaks in two institutions, it would appear that the incidence in the State as a whole will be greater than usual throughout the year

Typhoid fever shows as yet no decrease over last year's record low incidence

The reported incidence of lobar pneumonia was higher than it has been for February since 1929

Tuberculosis morbidity is running somewhat lower to date than in 1935

Mumps continues to be reported in record breaking figures

Scarlet fever continues to run higher than for the past two years

Whooping cough had its lowest reported February incidence

The incidence of anterior poliomyelitis, chickenpox, measles, German measles, and tuberculosis other forms was not remarkable

COMMITTEE FOR THE STUDY OF SUICIDE

An organization to be known as the Committee for the Study of Suicide, Inc., was incorporated last December under the laws of the State of New York and began its activities early in January. The Committee may in time increase its present membership of ten to a total number of twenty. The Board of Directors and the officers of the new corporation are the following: Dr. Gerald R. Jamieson, President, Mr. Marshall Field, Vice-President, Dr. Henry Alsop Riley, Treasurer, Dr. Gregory Zilboorg, Secretary and Director of Research, Miss Elisabeth G. Brockett, Dr. Franklin G. Ebaugh, Dr. Herman Nunberg, Dr. Dudley D. Schoenfeld, Dr. Betina Warburg

The Committee plans to undertake a comprehensive study of suicide as a social and psychological phenomenon. To achieve this the following general outline was adopted:

1 *Intramural studies* of individuals inclined to suicide in selected hospitals for mental diseases. These will embrace constitutional, neurological, psychiatric and psychoanalytic investigations of the phenomenon with special reference to therapy and prevention. This part of the study will include the investigation of suicidal trends or ideas of death emerging in organic deliria.

2 *Extramural studies* of ambulatory cases afflicted with suicidal trends or with obsessional wishes for their own death. These studies will be primarily therapeutic in nature, the cases to be treated in especially selected out-patient clinics and by qualified psychiatrists and psychoanalysts. Regular "control seminars" to follow and to supervise the course of the cases under treatment will be held

under the guidance of the Committee. The medical and neurological status of all cases will be a prerequisite of each case record.

3 *Social studies* of suicide will be undertaken along the following general lines. Various attempts at suicide will be followed up by experienced psychiatric social workers all cases will be studied from the standpoint of social background and history and those who failed in their attempts or have recovered from injuries following a partially unsuccessful attempt (prolonged unconsciousness or physical illness) will be urged to submit to psychiatric and psychoanalytic treatment in the hands of the intra or extramural therapeutic agencies which will be available to the Committee.

4 *Ethnological studies* i.e., comprehensive investigation of suicide among primitive races will be one of the first concerns of the Committee for suicide is a rather frequent occurrence among many primitive races still extant and when studied may throw some light on suicide as a psychobiological phenomenon. It is planned that an expedition headed by a psychiatrically schooled anthropologist, a psychiatrist and a psychoanalyst should work for a time in a region such as the Malanesian Islands or the Gulf of Papua, and in the interior of the Mexican North West as well as among some of the North American Indian tribes. Further details of this plan will be elaborated.

5 *Historical studies* of suicide will be pursued systematically under the auspices of the Committee so as to make available a scientific history of this phenomenon as a social and medicopsychological problem.

The Committee was organized under the guidance of its first chairman the late Dr Mortimer Williams Raynor Medical Director of Bloomingdale Hospital who died on October 5, 1935.

Dr Henry E. Sigerist, Professor of the History of Medicine at Johns Hopkins University and Dr Edward Sapir Professor of Anthropology at Yale University are consultant members of the Committee. They will advise and guide in that part of the work which touches their respective fields.

The Executive Offices of the Committee are located at Room 1404 the Medical Arts Center 57 West 57th Street, New York City and will be in charge of an executive assistant.

CORRESPONDENCE

SENATE BILL 394

Board of Registration in Optometry
State House Boston

March 16 1936

Editor *New England Journal of Medicine*

In your issue of March 12 there is an article calling attention to the danger inherent in Senate Bill 394. I do not question the sincerity of the writer but his article shows a complete misunderstanding of the bill, even as it is printed. I would

greatly appreciate the courtesy if you will publish this statement of fact.

The sponsors of this bill have no desire to encroach upon the privileges of the medical profession in their desire to correct an abuse which has crept into the practice by virtue of the exemption of application of the law to physicians. The language of the original bill was such that physicians would be subject to the rules of optometric procedure in an examination of the patient. We can see just cause for protest on the part of physicians to this regulation on principle alone and since the matter was called to our attention after consultation with some of the leading ophthalmologists of Boston we have eliminated the objectionable phrase "subject to rules or regulations governing the practice of optometry" and inserted in its place "subject to rules pertaining to advertising." This phrase is necessary to take care of the situation where a few unethical physicians are prostituting the profession by the use of their certificates in the practice conducted by these unscrupulous commercial concerns and surely no ethical physician would protest at the regulation of his advertising by anyone he be physician, optometrist or optician. The bill in every other particular does not affect physicians they are exempt from the provisions of the bill in the original law and in these proposed amendments they are also exempt from all of the provisions of the law save this one pertaining to advertising. I would respectfully refer any physician who questions the accuracy of the above statements to consult with some of the leaders of the New England Ophthalmological Section for verification of these statements. There will be a hearing on March 19 and we would welcome the attendance of any physician to hear our presentation of the case with an open mind and thus be reassured of our honesty of purpose, and of the fact that no ethical physician has reason to protest the enactment of his legislation. Thanking you for the courtesy of your columns I am

Very truly yours,

JOHN E. CORBETT Chairman

Massachusetts Board of Registration
in Optometry

EDITORIAL NOTE: An agreement has been reached at a meeting of physicians and optometrists for an amendment to this bill which is satisfactory to both parties.

COEXISTENCE OF APPENDICITIS AND MEASLES

March 17 1936

Editor *New England Journal of Medicine*

The current increase in the normal average number of cases of measles reported from certain communities in Eastern Massachusetts together with a recent experience prompted me to call attention again to the coexistence of acute appendicitis and measles.

In this Journal for April 12, 1934, a letter was published in the correspondence section in which I reported several personal experiences with measles and appendicitis. A month after this letter appeared I saw another child, aged five, who was taken ill on May 7, 1934, with measles. On the evening of May 10 she vomited. On May 11 she seemed more ill than she had been during the preceding three days. On May 12 she complained of abdominal pain and there was more vomiting. On May 13, the day on which I saw her, she again complained of abdominal pain. Her examination at that time revealed the presence of an appendix abscess. She was operated upon that day and a retrocecal perforated appendix with abscess formation was found. The appendix was removed and the abscess drained. She made a gratifying convalescence.

At about this same time a five-year-old boy was seen by one of my friends. This child complained of abdominal pain and had been vomiting for several days. His examination was suggestive but not diagnostic of appendicitis. There was a leucopenia, and Koplik spots were seen on his mucous membranes. He was observed for twenty-four hours during which time he developed signs of peritonitis. He was operated upon and the peritonitis found to be of appendiceal origin. This patient died.

On March 14, 1936, I saw a girl of eight who was taken ill early in the morning with vomiting. She vomited throughout the morning and the early afternoon. There was no complaint of abdominal pain. When seen by her physician at one-thirty P.M. on March 14 her temperature was 99° and the physical examination was considered negative except for slight redness of the throat and slight injection of one ear drum. At four-thirty P.M. she complained of abdominal pain for the first time. At six-thirty P.M. she was seen by her physician who made a diagnosis of acute appendicitis. Operation was performed at nine-thirty P.M. and an acutely inflamed appendix removed. The lumen of the appendix was distended with pus. Following operation on March 14 her convalescence has been satisfactory except for the presence of slight fever. She vomited once the evening of March 15 and once the afternoon of March 16. This afternoon a diagnosis of measles was established.

As pointed out in the letter of 1934 this experience has been noted by others, chiefly in foreign literature. A review of the subject with six reported cases appears in the *Archives of Pediatrics* for January, 1933.

This letter is written in the hope that practitioners seeing children with measles who present signs suggestive of appendicitis will give consideration to the latter as a probable diagnosis, as in the eight cases of which I have personal knowledge all but one had perforated before operation, with the result that two of the eight children died.

Brookline, Mass

SURGICAL OPERATION FOR HIGH BLOOD PRESSURE

March 16, 1936

Editor, *New England Journal of Medicine*,

Your editorial of March 12, "Surgical Operation for High Blood Pressure," is timely and justifiably conservative in regard to this new therapeutic approach to a very common disease. Your plea for more experimental work and less surgical trial is, in general, appropriate. However, the employment of certain surgical procedures in my opinion is justified in carefully selected cases after all the resources of a thorough medical régime including psychotherapy have been exhausted.

To date the surgical procedure of choice is dorsal sympathectomy or possibly as suggested by the Mayo Clinic¹ splanchnic resection and partial adrenalectomy. Laminectomy and anterior root section appear to carry too great a mortality and too great a risk of postoperative complications. Some experimental work² has been interpreted as demonstrating that surgery of the sympathetic nerves will not be effective. The work of others³, and the experience of Dr R. H. Smithwick and myself, as yet unreported, nevertheless show that operative procedures are effective in lowering the blood pressure in certain cases during postoperative periods of months up to slightly over two years.

The selection of cases is most important. After the menopause in women and over forty-five years of age in men, essential hypertension pursues a long and benign course lasting ten to twenty years, during a large part of which the disease is either asymptomatic or symptoms are favorably influenced by simple measures. Essential hypertension in young males, or vasomotor instability with transient rises in blood pressure often spontaneously subsides or is readily controlled. On the other hand, rarely in young males, but more often in young females before the menopause, in certain constitutional types, observation reveals an intensity, a rapidity of progress, and a failure to respond to treatment which suggests the approach or onset of the malignant phase of essential hypertension. If abnormal catamenia, sterility, or toxemia of pregnancy occurs in the anamnesis one is more inclined to a grave prognosis. If such a patient under careful treatment shows progress of the disease I believe the use of a relatively safe surgical procedure with a reasonable prospect of success may be offered with full explanation to the patient.

BIOLOGICAL PROBLEMS OF STERILIZATION

To the Editor of *The New York Times**

Without entering into the controversy on sterilization in any direct sense, let me state briefly the fundamental facts uncovered by the committee of the American Neurological Association and its conclusions and recommendations.

We find the claims of most eugenicists as to the incidence of mental disease and mental defect unwarranted. There is no evidence of an actual increase. The entire biology of the situation is opposed to any real increase. Thus, it is not true that the feeble-minded have large families or are more prolific than the general population, nor is this true of the insane.

All the facts indicate quite clearly that there is a low marriage rate, a relatively low birth rate, a high death rate and even a high divorce rate. This is not only our opinion but also that of the British commission. That the biological setting is directly against any increase of the incidence of mental disease and mental defect is brought out by an actual analysis made not only for the United States but the world by Dr. Ellen Winston. The only present increase in mental disease in any of the cultural countries relates to the incidence of the senile mental diseases and this is undoubtedly due, first to the greater age of the population accounted for by the lower birth and death rate and second to the fact that as hospitals grow better people are more ready to send their aged sufferers to institutions for mental disease.

MYTHICAL MONSTROSITIES

The Nams Kallikaks, Jukeses and similar families are in the opinion of the British commission and of the American committee, more or less mythical monstrosities which are probably largely social in origin.

Certain physical and mental diseases may be stated to have a hereditary basis. A few rare bodily diseases such as Huntington's chorea, hereditary blindness and deafness, are unquestionably of genetic origin. The main mental diseases with which eugenic legislation is concerned are manic-depressive psychosis, dementia praecox, epilepsy, feeble-mindedness and, by a stretch of the term mental disease, criminality.

While there is no hereditary basis in the case of manic-depressive psychosis and dementia praecox, it can safely be stated that the mechanism of heredity is entirely unknown. The inheritance of these conditions is not classically Mendelian, probably some environmental factor is at work as well as the hereditary one. The attempt to prevent these diseases by sterilizing those who themselves are not sick would be futile. Furthermore, sterilization would not greatly reduce their incidence. In a certain sense, dementia praecox sterilizes itself. Those who suffer from it have a low marriage and birth rate and tend to early incarceration in hospitals.

Of feeble-mindedness it can be directly stated that

Reprinted from *The New York Times* (March 16, 1926)
by permission.

a large proportion is of hereditary origin. Yet the mechanism of inheritance is debatable and does not conform to Mendelian ratios or any modification thereof.

THE CASE OF EPILEPSY

Epilepsy can be practically speaking eliminated from consideration as hereditary. At the last meeting of the International Neurological Bodies in London the statement was made directly by several of the readers that environmental difficulties could be assumed to create the disorder.

As in criminality none of the important geneticists believe that sterilization would have any effect that, whatever constitution is involved, criminality is so linked up with culture, economics, tradition and the pressure of the complex social environment as to preclude sterilization as a defensive weapon.

Our committee takes note of the fact that considerable genius is associated with mental disease, that especially is the manic-depressive temperament closely related to superior ability and that any sterilization procedures which operate blindly and without taking into account the total assets of the personality may do more harm than good. It becomes quite obvious from a study of literature that much genius would have been lost if drastic sterilization laws had been enacted in times past.

This committee therefore recommended in essence as follows:

1. That on the American scene compulsory sterilization is futile and only voluntary selective sterilization laws can be recommended, this to apply to inmates not only of State institutions but of private institutions and to individuals in the community at large. This might reasonably apply to those cases of feeble-mindedness of definite hereditary origin but even here the assets of the personality in other directions might well be considered.

SELECTIVE BREED

2. That in the case of manic-depressive psychosis there should be a very careful weighing of the individual case and of the total personality assets and liabilities. In other words we recommend strongly selective sterilization as the only legitimate legislation here to be considered.

3. This applies although in lesser degree to dementia praecox.

4. In so far as epilepsy is concerned we are strongly opposed to any sterilization on the basis of heredity although there may be a reason why an individual who has epilepsy should be voluntarily sterilized because of other difficulties he encounters. The committee is opposed to sterilization for social reasons or social difficulties largely because of the danger of forging a weapon which would be used by the unscrupulous for punitive and prejudicial purposes.

5. In so far as crime is concerned this committee is wholly opposed to sterilization believing that it is only a form of punishment, a sort of dodging

of the issue, and a shifting of the responsibility from society to the germ plasm

The crying need of eugenics, as this committee sees it, is not legislation but real research. There have been no researches which fully merit the term scientific. The difficulties are great and they require a large organization with a systematic study, especially control studies, carried over a period of fifteen to twenty-five years. While we recommend a limited legislative program, our main recommendation lies in the direction of more fundamental, more thorough and more impartial research.

ABRAHAM MYERSON, M.D.,

Chairman, American Neurological Association Committee for the Investigation of Sterilization.

Boston, Mass., March 10, 1936

RECENT DEATH

McALLISTER—FREDERICK DANFORTH McALLISTER, M.D., of Methuen, with an office at 301 Essex Street, Lawrence, died at the Lawrence General Hospital, March 17, 1936.

Dr McAllister, the son of Dr John D McAllister, was born in Lawrence in 1872, attended Amherst College and graduated from the Harvard Medical School in 1898. His Internship was served at the Worcester City Hospital.

He was a Fellow of the Massachusetts Medical Society and the American Medical Association and had been prominent as a surgeon and consultant.

His widow, a daughter, two sisters and a brother survive him.

NOTICES

THOMAS WILLIAM SALMON MEMORIAL LECTURES

The Salmon Committee on Psychiatry and Mental Hygiene invites the medical profession and their friends to the Fourth Series of Thomas William Salmon Memorial Lectures to be given by Samuel T. Orton, M.D., Friday evenings (8:30), April 10, 17, 24, 1936 at the New York Academy of Medicine, 2 East 103rd Street, New York City.

Developmental Disorders of the Language Faculty and Their Psychiatric Import

Lecture I Language Losses in the Adult as the Key to the Developmental Disorders in Children (April 10)

A discussion of the physiological background of the language faculty as revealed in the aphasias. The problem of unilateral cerebral dominance. Reports of studies indicating that all degrees of intermixture occur between right and left-sidedness. Such intergrading between the hemispheres is suggested as the background for many language disorders in children.

Lecture II The Syndromes of Disorder in the Development of Language (April 17)

Six syndromes are discussed from the point of view of their symptomatology. Reading Disability (strophosymbolia), developmental word deafness, congenital apraxia, motor speech delay, writing disability, and stuttering.

Lecture III Treatment and Psychiatric Interpretation (April 24)

A brief review of the general principles of treatment of the various syndromes, together with a discussion of the relation of these conditions to emotional and mental development.

Thursday April 30—Some Practical Aspects of Tuberculosis
Dr C H Whitehurst.

REPORTS AND NOTICES OF MEETINGS

FORTY YEARS OF XRAY

On Thursday January 23 1896 the fortieth anniversary of Professor W K Roentgen's discovery of the x-ray was commemorated in the Moseley Memorial Building of the Massachusetts General Hospital. Dr W B Breed presided and commented on the modesty and sincerity of Professor Roentgen and on his enormous capacity for work.

Dr Francis T Hunter reviewed the main events of Roentgen's life. He was born in 1845 and it is not definitely known whether he was a citizen of Holland or Germany. He was not particularly brilliant, and because he was refused entrance to the gymnasium, he gained his early education in the Polytechnic School of Zurich. He received his doctorate of philosophy from the University of Würzburg in 1871 but could not gain academic promotion in that school because of his unfamiliarity with Latin.

He moved to the new University of Strassburg in 1876 where he was an instructor in physics and performed important researches on gun metals. Because of his excellent work he became well known academically and was offered the chair in physics at the University of Utrecht, a school which had refused him entrance as a student. He declined this appointment, and in 1888 accepted the professorship of physics at the University of Würzburg where he had previously been denied advancement because of his lack of knowledge of Latin. In 1895 he began his experiments on cathode rays which were to lead to his discovery of the x-ray.

On December 20 1885 his paper *Ueber eine neue Art von Strahlen* appeared in the *Beiträge zur Physik der Würzburger Physik-medizinischen Gesellschaft*. Even before this periodical was distributed, reprints had been prepared and news of his discovery had reached the press, and been widely publicized over the whole of the civilized world. It was not until January 23, 1896 that he delivered his paper before a large audience of academics and high government officials.

In 1890 he became professor of physics at Munich and was awarded the Nobel Prize in physics in 1901. He received some fifty honorary degrees from various universities all over the world before his death in Munich on February 10 1923 at the age of seven ty-eight years.

The discovery of the x-ray must be considered with the discovery of ether anesthesia, and the bacterial etiology of disease as one of the three greatest contributions to the medical knowledge of the world to be made in the nineteenth century.

Dr E. A. Codman spoke on *Reminiscences of Early*

X-Ray Work in Boston. The announcement of the x-ray and its properties aroused a vast amount of skepticism and the first review of the work in the *Boston Medical and Surgical Journal* of February 13 1896 was extremely conservative in its comment. Dr Codman published an article in this Journal March 20 1886 with reproductions of x-ray plates of a full-term fetus, showing the varying calcification of different bones and the ossification centers. Four months elapsed after Roentgen's announcement of his discovery before practical application of the rays were made in Boston when on April 13 1886 Dr Codman took an x-ray photograph of a hand in which a shoemaker's head was imbedded.

A double focus roentgen tube was secured from England in May 1896 which greatly aided in photography of the deeper structures and studies of the heart and lungs were made by Dr Francis Williams in October of that year. Investigations of the effects of x-rays on tissues were first made in September by Dr Seabury Allen, and Dr J C White first reported x-ray burns in December of 1888. The story of the earliest use of the x-ray in Boston, the first description of x-ray dermatitis, the first report of the effect of radiation on the tissues are all contained in the 1896 volume of the *Boston Medical and Surgical Journal*.

Mr Joseph Goodson who worked in the x-ray department of the Massachusetts General Hospital from 1896 to 1909 spoke of his experiences with the various forms of apparatus in use at that time and paid tribute to Dr Walter Dodd one of the first martyrs to the advancement of x-ray.

Dr George W Holmes roentgenologist at the Massachusetts General Hospital since 1911 spoke on *The Present Status of Radiology in the Treatment of Cancer*. Dr Holmes reported a case of carcinoma of the hip which he treated in 1910 with fractional doses of radiation over a considerable period of time. This patient was followed for ten years, with no signs of recurrence. In the application of radiation therapy it is important to consider the age of the patient, the size, location and malignancy of the lesion to be treated. The problem in treating lesions lying beneath the surface of the body is to give these lesions the greatest possible dosage with as little damage as possible to the overlying tissues. The dosage to the surface is always greater than the depth dose, with increasing voltage there is an increase in the depth dose with increasing distance between the patient and source of the rays, the radiation received by the deeper tissues approaches the amount received at the surface. The upper limit of increased penetration due to voltage increase is reached at about 500 KV, and 80 cm. is the maximum distance at which treatment is practical.

When extremely high voltages are employed in treatment, the character of ionization within the tissues is changed and as a result the therapeutic effects may be different from those obtained with lower voltages. The data at present available do

not indicate that these results will be superior, however

The degree of malignancy is of importance in determining the value of radiation therapy, in a given case. Many highly malignant tumors are easily destroyed with but slight injury to surrounding tissues. They are prone to metastasize early, however, and are seldom cured. Tumors of low malignancy are more radioresistant, and effective radiation does more damage to surrounding tissues, but due to the relatively late occurrence of metastases, results obtained in treating such lesions are often better than those in the more radiosensitive group.

Clinical experience is of the utmost value in applying radiation therapy. No tumor should be treated with massive dosage until absolutely proved to be malignant. Consultation service is considered necessary in every case, and only after the diagnosis has been established, the consultant has expressed his opinion, and a definite course of procedure has been adopted, should therapy be instituted. A plan of treatment once adopted should not be varied without further consultation, and thorough consideration. The tumor clinic with a staff of physicians of several different specialties each seeing the case is of distinct value.

It must be remembered that the tissues of children and youthful persons are more easily injured by radiation than those of elderly persons, and that growth processes may be permanently arrested by radiation.

Treatment may be undertaken with the hope of curing the patient, or as a means of palliation, that is relief of distressing symptoms. Treatment should be refused in cases with incurable disease which do not suffer disturbing symptoms, since radiation may only make such patients more uncomfortable, and is unjustified.

The question of preoperative radiation treatment with the hope of making more cases operable has recently been revived. If a case is inoperable, radiation will not make it operable. Cases which are inoperable because of their inaccessibility to surgical approach may be benefited and sometimes cured by radiation. Occasionally a case can be made "safer" for operation, e.g., large kidney tumors may be reduced in size, or the danger of rupture and peritoneal implantation of certain ovarian tumors may be minimized.

Postoperative radiation treatment is not logical. If the lesion cannot be removed by surgical means it should not be operated upon but treated with radiation alone, and if it can be removed completely there is no reason for postoperative radiation. If an attempt at complete removal fails and tumor tissue is left behind, treatment should be carried out as though there had been no operation.

Preradiation care is of importance. Local treatment should eradicate infectious processes, especially in the mouth. Bad teeth should be removed before radiation is begun, and not after, since radiated tissue is peculiarly susceptible to serious infection. The general condition of the patient should

be improved as much as possible. Food and fluid intake should be adequate, and anemia should be alleviated. Necessary postoperative radiation should not be instituted until sufficient time has elapsed to allow complete recovery from the ill effects of operation. During treatment a high carbohydrate diet, and sufficient fluid intake, should be maintained, and every effort made to prevent the psychic suggestion of possible radiation sickness. If, in the treatment of the lesion, epilation is produced, skin ointments should be used only with caution, since they prevent the evaporation of perspiration, elevate the skin temperature, and aggravate the reaction. If heavy treatment is directed to tumors in the upper respiratory passages, facilities for the performance of tracheotomy must be at hand.

There are three types of "roentgen sickness." The first is of psychic origin, and is often eliminated by the substitution of radium for x-ray, or vice versa, or by referring the patient to another laboratory. The second type is due to "intoxication" from tissue breakdown, and can be treated in the manner employed in the treatment of other "toxic" conditions. "True" roentgen sickness, which is of unknown etiology, has many features suggestive of liver dysfunction. Treatment of this condition with a high carbohydrate diet definitely aids some cases.

The belief that high voltage is more likely to cause radiation sickness than low voltage is false. The development of roentgen sickness is independent of the voltage used for the treatment, and depends upon the total area treated, the location of this area and the dose administered.

Dr Holmes believes that advance in the field of roentgen therapy will be made through variations in the duration of treatment, and fractionation of dosages, rather than by use of extremely high voltages.

THE BOSTON PATHOLOGICAL SOCIETY

The stated meeting of the Boston Pathological Society was held in the Pathology Laboratories of the Infants and Children's Hospitals on Wednesday evening, February 19. The first part of the evening was devoted to an exhibition and demonstration of interesting pathological specimens obtained at the Infants' and Children's Hospitals and from members of the society.

Following this, the meeting was formally called to order by Dr. Monroe J. Schlesinger, President, and a series of papers was read. Dr. Robert Fienberg of the Pondville Hospital in Wrentham discussed his recent work in determining the actual mechanism of the Smith-Dietrich lipid stain, as well as further studies he is conducting in staining various members of the lecithin phosphatide groups. Then there were four papers on various unusual and bizarre types of tumors. The first presentation was by Dr. B. Earl Clarke of the Rhode Island Hospital, Providence, on "Retinal Tumors in Tuberous Sclerosis." Dr. Clarke reviewed the literature and showed lantern slides demonstrating the microscopic ap-

pearance of a case of retinoid tumor in this disease. The nature of the tumor cell was discussed in some detail but its exact origin was not definitely determined. Perhaps it is related to the primitive cells from which the rods and cones originate.

Dr Paul Harris of the New England Deaconess Hospital reported a case of onkocytoma of the parotid gland. In discussing this particular tumor Dr Harris pointed out that so-called onkocytes which are large granular swollen cells occur in the mucous and serous glands in the mouth in older persons only. While the exact nature of the cell is not known, it may represent the result of the process of so-called dedifferentiation. Rare though the cells are it is even more rare for them to become malignant.

Dr John Egoville presented a very interesting case of pheochromocytoma of the adrenal gland from the Rhode Island Hospital. The patient a young woman had had paroxysmal symptoms of hypersecretion of adrenalin and a tumor of the adrenal medulla was found and removed. Unfortunately the patient died following operation. The last case was a presentation by Dr Edward Bosworth of the Rhode Island Hospital, in which there were primary mesothelioma cells studded throughout the pleural pericardial and peritoneal cavities.

Following the scientific meeting members and guests adjourned for refreshments.

CARNEY HOSPITAL CLINICAL MEETING

The next meeting will be held Friday evening April 3 at 8:30.

Subject: Chronic Nephritis. Dr James P. O'Hare. Physicians and medical students are invited.

FAULKNER HOSPITAL CLINICAL MEETING

The next meeting will be held on Thursday April 2 at 5:00 P.M.

In addition to the usual clinical pathological conference Dr Frederic J. Cotton and Dr Henry C. Marble will talk on Reconstruction Surgery—Joint, Bone and Tendon.

All physicians are invited.

THE NORFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the society will be held in Hotel Kenmore Boston Tuesday evening March 31 1936. Tel. Ken. 2770.

Business Meeting 7:30 P.M. Chairmen of committees are asked to bring in reports.

Communication 8:15 P.M.

Cauterization of the Cervix Uteri Using Various Electrical Methods. Illustrated. Dr Benedict F. Boland.

Discussion.

Collation.

Brookline Mass.

BOSTON HOSPITAL COUNCIL

The first Annual Meeting of the Hospital Council of Boston will be held in the Lower Amphitheatre of the Out Patient Department of the Massachusetts General Hospital on Monday April 6 1936 at 4:30 o'clock.

The business to come before the meeting is:

1. Election of officers
2. Adoption of proposed amendments to the Constitution and Bylaws a copy of which is presented below
3. Report of the Treasurer
4. Report of the President of special activities during the past year
5. Dr. Wilinsky will report on his personal impressions of the Medical Economic Security Council of Washington

Since this is the first opportunity the Officers and Executive Committee have had to make a report of their activities to the entire Corporation it is hoped that all members will make a special effort to be present.

J. B. HOWLAND M.D. President

PROPOSED AMENDMENTS TO THE CONSTITUTION AND BYLAWS OF THE HOSPITAL COUNCIL OF BOSTON TO BE ACTED UPON AT THE ANNUAL MEETING ON MONDAY APRIL 6 1936

Article VI Elections shall be amended so to read Article VI Elections

Section 1 (Amendment.) The officers and members of the Executive Committee to be elected at the Annual Meeting shall be nominated by a Nominating Committee appointed by the President one month before the Annual Meeting but at the Annual Meeting nominations may also be made.

Section 2 (Amendment.) All vacancies for office shall be filled at the Annual Meeting election to be by ballot unless otherwise ordered.

Section 3 The representatives of the organizations in the Council membership shall be elected or otherwise designated annually by their respective organizations and notification of their selection sent to the Secretary of the Council at least seven days prior to its annual meeting.

Section 4 (Amendment.) In case a vacancy occurs in any of the offices or in the membership of the Executive Committee, the Executive Committee shall by ballot elect a person to fill such vacancy who shall hold office until the next Annual Meeting when such vacancy shall be permanently filled at the annual elections.

SOCIETY MEETINGS CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY MARCH 30 1936

Tuesday March 31—

8:15 A.M. Boston Dispensary, 5 Bennett Street,
Boston. Pediatric Case Presentation. Dr. Francis
McDonald.

- *12 M Boston Dispensary, luncheon meeting of the Clinical Staff Auditorium, second floor, Dispensary Building
- 2 30 P M. Pediatric Ward Vislt. Massachusetts Eye and Ear Infirmary
- 7 30 P M Norfolk District Medical Society Hotel Kenmore Boston

Wednesday, April 1—

- *9-10 A M. Boston Dispensary 25 Bennet Street, Boston Hospital Case Presentation Dr S J Thannhauser
- †12 M Clinico-Pathological Conference Children's Hospital.

Thursday, April 2—

- *8 30-9 30 A M Clinic, Surgical Staff of the Peter Bent Brigham Hospital, at the Peter Bent Brigham Hospital
- *9-10 A M Boston Dispensary, 25 Bennet Street, Boston Endocrine Clinic Dr C H Lawrence
- 5 P M Faulkner Hospital Clinical Meeting

Friday, April 3—

- *9-10 A M Boston Dispensary 25 Bennet Street Boston Lobectomy and Pneumonecctomy for Bronchiectasis and Tumors of the Lung Dr Richard H Overholt
- *8 30 P M Carney Hospital, Clinical Meeting

Saturday, April 4—

- *9-10 A M Boston Dispensary 25 Bennet Street, Boston Hospital Case Presentation Dr S J Thannhauser
- *10-12 Staff rounds at the Peter Bent Brigham Hospital

*Open to the medical profession

†Open to Fellows of the Massachusetts Medical Society

BOOK REVIEW

Human Pathology A Textbook Howard T Karsner Fourth Edition, Revised. 1013 pp Philadelphia and London J B Lippincott Company

The fourth edition of Dr Karsner's textbook maintains the standard of excellence set in the first. The well selected and up-to-date references are a useful feature of each chapter. The newer knowledge of various phases of the subject is well incorporated, particularly in the sections dealing with the ductless glands, the nervous system, and the hematopoietic system. The section on the general pathology of tumors has been very extensively revised and is one of the best discussions that it has been the good fortune of the reviewer to read. A number of illustrations, particularly of microscopic sections, are line and stipple drawings, inferior to good photomicrographs. The drawings of gross specimens, on the other hand, maintain an excellent standard. The division of the book into chapters in general pathology as compared with special pathology is a satisfactory one, which fits in well with most medical school courses.

VOLUME 214

APRIL 2, 1936

NUMBER 14

THE ROLE OF MENTAL HYGIENE IN GENERAL PRACTICE*

BY GILBERT STEIN, M.D.†

I. INTRODUCTION

"THE thing that hath been, it is that which shall be, and there is no new thing under the sun."

The doctrines of mental hygiene are no exception to this ecclesiastical rule. Such proverbs as, "Hope deferred maketh the heart sick" (Prov. 13:12), "Better is a dinner of herbs, where love is—" (15:17) "Better is a dry morsel, and quietness therewith than a house full of sacrifices with strife" (17:1), and, "A merry heart doeth a good like a medicine—" (17:22), indicate that the new science of the prevention of mental ill health is little more than a repetition of ancient truths many of which have been forgotten in our all too busy lives.

Even the modern emphasis upon child guidance, the most promising field of mental hygiene, was anticipated some four hundred years ago by the Aztec Indians¹ who laid down the following cardinal rules for the guidance of their children: "(1) The avoidance of gormazing and the careful regulation of food, (2) the avoidance of idleness, (3) strict punishment and (4) vocational training."

Moreover, the following additional excerpts from the Book of Proverbs indicate that the Aztecs, in turn, were anteceded by at least two thousand years by the writers of the Old Testament. Even a child is known by his doings—

(20:11), "—but a child left to himself bringeth his mother to shame" (29:15) "Foolishness is bound in the heart of a child, but the rod of correction shall drive it far from him" (22:15) "Train up a child in the way he should go, and even when he is old he will not depart from it" (22:6).

There is nothing new in mental hygiene, then except perhaps the somewhat tardy recognition that children, though small, have sensitive personalities of their own, with a desperate need for sympathetic understanding. It is this need which modern child guidance aims to supply thereby offering the most hopeful avenue of approach to the problems of social maladjustment and personal unappiness.

II. HISTORICAL NOTE

In addition to the proverbs quoted above, the great Chinese philosopher Confucius (550-478 B.C.), in his inclusive character "shu", laid down what is probably the most valuable rule in the whole realm of human relations: "What you do not like when done to yourself, do not do to others."²

A thousand years later Caelius Aurelianus (500 A.D.) anticipated the fundamentals of twentieth century psychiatry by placing his patients "under the best conditions of light, temperature, and quiet and recommended that everything of an exciting character should be excluded. Of particular interest are his references to tactfulness in attendance for the avoidance of antagonism, and to the limited and cautious use of physical restraint—theatricals, entertainment, riding, walking, and work were all recommended, particularly during convalescence—He denounced semi-starvation, bleeding, chains, and excessive drug therapy."³

Another nine centuries elapsed before the establishment of the first mental hospitals at Granada, Spain, and Bethlehem ("Bedlam"), London in 1403, but not until 350 years later did modern mental hygiene begin in earnest, when in 1751, through the combined efforts of Benjamin Franklin and Dr. Thomas Bond, a prominent physician of Philadelphia, a charter was obtained for the first hospital in America for the care and treatment of the insane. This was opened in Philadelphia in 1752 and for thirty years Dr. Benjamin Rush, Chemist, Surgeon, and Revolutionist, "the father of psychological medicine in America, was the skilled physician and faithful friend of all its patients."⁴

Still later 1792 Philippe Pinel, a French pathologist and internist, startled the medical world in Paris by removing the chains from the insane patients at the Bicetre, while in 1796 William Tuke and Lindley Murray opened the York Retreat in England.

The nineteenth century gave us Dorothea Dix (1802-1887) a Massachusetts school teacher and philanthropist, who was responsible for the founding of many state mental hospitals in the United States.

Finally, in the twentieth century Dr. Thomas W. Salmon, first Medical Director of the Na-

*Read in part before the Hampden County Medical Society, September 25, 1935.

tional Committee for Mental Hygiene, and Dr Adolph Meyer, Professor of Psychiatry at Johns Hopkins and early adviser to the National Committee¹², together with a score of other renowned psychiatrists many of whose works have been drawn upon for this compilation (see references), are the leaders who have helped to materialize some of the principles set forth by Caelius Aurelianus, fourteen hundred years ago

Mr Clifford W Beers¹, secretary of the National Committee for Mental Hygiene (1909) is largely responsible for the popularization of the aims and doctrines of mental hygiene which is gradually changing the attitude of the general public to one of tolerance for the insane, and to a realization that "psychiatry has at last changed from a descriptive science carried on, for the most part, by individuals whose main preoccupation was the kindly and pessimistic custody of deteriorated persons, to a science led by men (who are) vividly interested in education, delinquency, sociology (psychology), and other stimulating and hopeful approaches to the problem"¹⁶

III ORIENTATION

Menninger describes a healthy mind as "—the ability to maintain an even temper and alert intelligence, socially considerate behavior, and a happy disposition" It therefore implies "—the adjustment of human beings to the world and to each other with a maximum of effectiveness and happiness"¹⁸ We may define mental hygiene as the prophylactic branch of psychiatry which deals with the preservation of mental health

"Seven hundred thousand persons in this country now going daily about their work and play, and apparently well adjusted, are definitely ticketed for state mental hospitals within the next ten years (This conclusion is based upon statistical evidence, and presumes no increase in the admission rate of about seventy thousand patients per year to our mental hospitals) To find these persons long before they reach the stage of frank madness, and to discover and abort the illness if possible, is the aim of mental hygiene"¹³

Fortunately, the general practitioner is in an enviable position to accomplish this aim For, as Hunter²⁰ says, "The family physician occupies the unique position of doctor, general advisor, friend and confessor and he needs must be at least a little of each of these He enjoys an intimacy that affords an unparalleled advantage in approach He knows the family constitution through personal observation He knows all the family skeletons and the present and past reactions to them He knows the family morale and the individual capacity for intelligent cooperation For these reasons it would

seem economic and proper for this line of first defense—the family doctor—to be better prepared to deal with the question and to evaluate anew the neuropsychiatric factors of ill health and disease"

Lest it be thought that this is anything new in teaching ideals it may be well to note the remarks of Jacobi in the first presidential address before the American Pediatric Society in 1889, "Unless the education and training of the young is carried on according to the principles of a sound and scientific physical and mental hygiene, neither the aims of our political institutions will ever be reached nor the United States fulfill its true manifest destiny—of raising the standard of physical and mental health to possible perfections" Forty-six years later, Fife¹³ continues to hope "My simple plea in this paper is to urge that pediatricians become more conversant with the educational, social, psychologic and psychiatric phases of child health, so that they may become worthy preceptors and consultants in the homes—family advisors for children—and so that they may remain leaders in all activities directed toward the promotion of child welfare This pediatric parental preceptor is still in his infancy—"

Nevertheless the family doctor is already doing commendable work along preventive lines, in an effort to keep down the incidence of mental disease He is competent in the prevention of the exanthemata and their sequelae as well as in the realms of rachitis, meningitis, cretinism, syphilis, alcoholism, vitamin deficiencies, and many other diseases which have neuropsychiatric complications He is alert to recognize the need for prompt treatment of such congenital defects as cleft palate, harelip, webbed or supernumerary digits, cryptorchism, tied tongue, or any other anomaly or blemish which may be significant from a physiological as well as psychological viewpoint He is able to recognize a psychosis, often even in its early stages and is usually prompt in referring it to the psychiatrist for treatment, while he himself does well enough with the ordinary acute psychiatric complications of alcoholism, puerpera, and fevers He is becoming more and more adept in the art of psychotherapy, in the use of a polished bedside manner and a sympathetic attitude, as well as the well-known "tonic" (color rubro) He knows the value of a thorough physical examination in the treatment of the psychoneuroses which, as is well-known, constitute a large portion of his private and clinical practice (thirty to sixty per cent according to Pratt)²¹ and which cases he usually sees long before they reach the internist or psychiatrist He knows, too, the wisdom of merely allowing the patient to talk out his problems, even though he seldom can afford to grant the necessary hours for such therapy Lastly, he is already adept

at prescribing, for temper tantrums and feeding problems, whether they are the result of overindulgence, "Motheritis", irregular habits, faulty discipline, or other causes.

But it is a comparatively recent doctrine even for psychiatrists, that the emotions and personalities, too, may be traumatized by neglect of the early manifestations of their disorders (Cannon, Crie, Freud).²²

Moreover society is now developing a "health consciousness" concerning mental hygiene that it has already acquired regarding many problems of public health and preventive medicine consequently "the intelligent layman (and his numbers are growing rapidly in every community) is more ready to avail himself of modern psychiatric service than ever before."²³

It remains, therefore, for the good physician to add to his therapeutic armamentarium merely a bowing acquaintance with child guidance, psychiatric social service, and psychometry and to become more familiar with their application to the problems of insecurity, vocational guidance, the unmarried mother, borderline intelligence, juvenile delinquency, and "emotional immaturity", in order to fill the cup of his specialized knowledge to overflowing. For as Frank aptly expresses it: "The great doctor must know almost as much about the social order as the sociologist. This is necessary because the varied forces—political, social, economic, industrial, educational, religious—that march across a nation, making its mind or marring its spirit, register their effects in the lives of the doctor's patients. The more the doctor knows about these forces that make the atmosphere in which men's minds and bodies live the more intelligently can he trace effects to their causes, and the more wisely can he counsel his patients."

"The great doctor must know almost as much about the mind as the psychologist. This is necessary because even the most materialistic scientist admits that there is a subtle relationship between mind and body that the doctor of the body dare not overlook, for when he does overlook this relationship a thousand quacks rush in to capitalize his oversight."

"The great doctor must know as much about the subtle art of counselling as the priest."²⁴

IV STATISTICS

One explanation of this increasing demand for psychiatric information and service may be the disproportionately small number of physicians who are engaged in the neuropsychiatric specialty. There are in the United States six hundred and thirty-one hospitals for the care of nervous and mental cases. It will be noted that the number of nervous and mental institutions is less than ten per cent of the total number of registered hospitals but that in capacity and number of patients, they represent nearly fifty per cent of the total.²⁵

The total number of physicians in this country is 178,516.²⁶ The number of physicians especially interested in neurology, psychiatry, or both is only 2,341 these include residents of mental hospitals.²⁷ Thus less than two per cent of the physicians of the United States are hurried with the care of fully fifty per cent of the sick population of the country, the bed cases of which alone number close to one million people. A similar disproportion exists in the nursing field in which only eight per cent of the training schools, and only five per cent of the student nurses in the United States are in mental hospitals.²⁸

Although it is true that, to a considerable extent every physician is a psychiatrist whether he wills it or not, it is also true that the busy general practitioner is only just beginning to make up some of the defects in his psychiatric education. This paper is designed to assist him with an introduction to the study of what has been termed the "Cinderella of Hygiene."

V A CLASSIFICATION OF PROBLEMS IN MENTAL HYGIENE

The common problems in mental hygiene may be divided conveniently (but arbitrarily) according to their appearance during the several periods of growth as follows:

- 1 Infancy—under two years of age, feeding difficulties, night cries, habit spasms, and the question of adaptability.
- 2 Childhood—from two to twelve years in corrigibility, enuresis, speech defects, retarded development, undue shyness, thumbsucking, nail biting, failure in school, pilfering, and sometimes masturbation, truancy and stealing.
- 3 Adolescence—from thirteen through the teen age vocational guidance, personality changes, problems of puberty, sex, and delinquency.
- 4 Adulthood—twenty-one years and over responsibility, personality, marriage and parenthood.

Each age group has specific problems of its own and each may be complicated by problems which should have been corrected previously but, instead, have been carried over from an earlier level in the expectancy that they would be outgrown. All of them, however, have certain underlying factors in common which may be grouped under the headings of security, sex, and maturity. Most important of these is security but an understanding of all these common denominators as determined for the specific case will serve to simplify the study of any given problem. For detailed accounts of the specific complaints listed in the classification above the interested student is referred to the standard works on specific phases of mental hygiene: child guidance, sociology and psy-

chology by Thom^{37 38}, White⁴¹, Campbell⁴⁵, Plant^{29 30}, Hart¹⁷, Wickes⁴², Myerson²⁷, Stearns³⁰, Glueck¹⁵, Huhner¹⁹, Landsay²⁴, Ellis¹⁰, Van de Velde³⁰, Westermarck⁴⁰, and scores of others^{2 3 30}, many of which are to be found in the extensive reading list by Levy and Coburn²³

VI ETIOLOGY

Factors involved in the causation of difficulties in behavior are classified by Lowrey²⁸ as follows

- 1 Gross mental deviations—feeble-mindedness, psychoses, encephalitis, lues, and tumors
- 2 Gross physical deviations—including deformities, and handicaps as of the senses, sight, hearing, etc
- 3 Psychoneuroses
- 4 Conflicts with individual drives against group thinking, group law, group morals, society, etc

"Problems in this group," says Lowrey, "do not always need a psychiatrist—they sometimes heal with time alone. Most of us manage to achieve some sort of compensation in our lives as we go along. We achieve some sort of balance in our personality, some maturity in point of view, some emotional poise. We manage in some way to make a fairly successful adjustment to life whereby we do not do too many things that distress other people, or at least we do not have any gross signs of failure of social adaptation. Here child study groups and church and education, the law, medicine, psychiatry, psychology, and so on, have definite contributions to make."

- 5 "Faulty training by ignorant parents (and teachers) is the simplest group to deal with," says Lowrey, "and child study organizations have made some real contributions to it."

VII TREATMENT

As in the treatment of tuberculosis and carcinoma there is an important time element and unavoidable cost. "The treatment of a disease may be entirely impersonal" (laboratory procedure, surgery, instructions to internes and nurses) "the care of a patient must be completely personal—and the failure of the young physician to establish this (intimate personal) relationship accounts for much of his ineffectiveness in the care of patients" wrote Francis W. Peabody nearly a decade ago. In "The Care of the Patient" this great internist presented the following principles for guidance and analysis of the situation:²⁸

- 1 "Sickness produces an abnormally sensitive emotional state in almost every one, and in many cases the emotional state repercusses, as it were, on the organic disease."

2 "Death is not the worst thing in the world, and to help a man to a happy and useful career may be more of a service than the saving of life."

3 Nausea, vomiting, diarrhea, tachycardia, occipital headache and gastric distress are symptoms that may accompany the nervousness attendant upon an impending examination, a forthcoming speech or public appearance, or participation in a sports contest—but they are just as distressing as though they were from some organic cause.

4 Ordinarily the symptom vanishes when the occasion for the nervousness has passed—but if instead of an important three-hour examination, e.g., the patient has to face a lifetime of disappointment, failure or hardship—then the factor of repetition fixes the unusual emotional viscerosomatic response into a conditioned habit and instead of saying "I cannot stand this life," the patient says, "I cannot stand this nausea and vomiting. I must go to see a stomach specialist," and thus the neurosis becomes securely established.

5 When thorough examination discloses entirely negative findings on such a patient "you are in the difficult position of not having discovered the explanation of the patient's symptoms. You have merely assured yourself that certain conditions are not present."

6 "Sorrow, disappointment, anxiety, self-distrust, thwarted ideals or ambitions in social, business or personal life, and particularly what are called maladaptations to these conditions—these are among the commonest and simplest factors that initiate and perpetuate the functional disturbances."

7 "Sometimes the mechanism of cause and effect is obvious, (backache in a woman on first experiencing domestic unhappiness, headache from unfulfilled ambitions, or a functional tachycardia from years of brooding over a functional murmur about which a physician once told the patient 'not to worry'), sometimes it becomes apparent only after a very tangled skein has been unraveled."

8 "Time, sympathy and understanding must be lavishly dispensed, but the reward is to be found in that personal bond which forms the greatest satisfaction of the practice of medicine."

Richardson, in a recent publication³³, presents some excellent illustrations of the clinical manifestations of these mechanisms. The following three cases from the Springfield Child Guidance Clinic are selected to illustrate the handling of three common and very troublesome problems, viz., incorrigibility, enuresis, and stammering or stuttering.

CASE 1 R (S H C G C No 10434), white boy, aged five and one-half years in first grade

A Complaint

- 1 Incurable and negativistic behavior
- 2 Unresponsive and failing in school.

B Relevant Data Mother was the ninth of ten children and led an unhappy early life. She was compelled to leave the seventh grade, and to work out as a mother's helper and has always longed for a chance to return to school. Her own mother who was always very strict and used to beat her together with two of R's maternal aunts both aunts came to live with R's family when he was only two weeks old and have remained there ever since.

Physical Findings 1 Defective tonsils 2 Cryptorchism (bilateral incomplete) 3 Malnutrition (15 per cent underweight, pot-belly slow pulse moist hands, cold feet) 4 Enlarged anterior cervical lymph nodes.

C Diagnosis

- 1 Retarded Intelligence (I Q 87—technically dull)
- 2 Chronic tonsillitis and anterior cervical lymphadenitis
- 3 Bilateral cryptorchism (incomplete)
- 4 Malnutrition (old rachitis and tonsillitis)

D Analysis 1 Mother's early deprivation of scholastic opportunities has caused her to place a high premium upon formal education so that she takes R's failure in school very much to heart. 2 Even if R were not emotionally handicapped by the divided disciplinary attempts of mother grandmother and the two aunts at home, his mental age of four years and eight months indicate that he is nearly a whole year retarded, and just ready to begin kindergarten let alone be finishing a regular first grade. 3 Father seldom interferes at home, but the irritable aunts and whining nervous grandmother require quiet, attention and implicit obedience from R as well as from his older brother and two younger sisters. 4 While the father has never protected the presence of his wife's relations in his home financial difficulties incident to the depression have made the mother conscience-stricken so that in addition to all the housework, she has more to strain her emotional composure than the average mother of four young children should have. 5 To top it all R's three siblings are all decidedly brighter than he is and this fact, together with the mother's high standards and his own inability to grasp first grade work (which normally requires a mental age of five and one-half to six years) cause him to appear stupid by comparison with his classmates, making his lot unenviable and his life miserable.

E Treatment The incurable behavior—temper tantrums, destructiveness, disobedience and feeding difficulties—are R's attempts to overcome his feelings of insecurity. Until efforts were made to convince him that he need no longer feel insecure despite his physical and intellectual limitations no real relief could reasonably be expected.

Removal of tonsils and an orchidopexy might assist him physically and the issuing of walking papers for grandmother and the two maiden aunts might make life more bearable at home but until the mother could lower her scholastic standards and become more willing to accept something less than an intellectual genius from R, only slight improvement could reasonably be expected.

Unfortunately truth often proves to be too shocking to ambitious parents, so that at first they may refuse to return to the clinic, resenting such suggestions as may threaten the security of their own ego. R's mother was no exception to this common rule so that not until after many months of intensive psychiatric social work followed up in her own home by a skilled and tactful worker did she finally con-

sent to taking R out of school whereupon the majority of the complaints promptly vanished. A year later back in school with a mental age more consistent with the demands of first grade, he has shown a vast improvement and even the mother has asked permission to return to the clinic for a check upon our findings and for further guidance.

CASE 2 B (S H C G C No 19275) white girl aged fifteen and a half years a sophomore in high school

1. Complaint

- 1 Nocturnal enuresis—duration nine years
- 2 Poor work in school.
- 3 Indifferent toward schoolmates associates with younger children plays with dolls cries easily

B Relevant Data Father the second of six children from all of whom he is estranged was the first son and the only one to go to college. He was formerly a successful professional man but has become irritable, asocial and quarrelsome. He is losing his patients as well as the respect of his friends and family. His preference for B's brother has turned her adoration to bipolar hatred for him. He never came to the clinic, or acknowledged our letters.

The mother is colorless, but cooperative and in contrast to the father has a very close tie with her two children as well as with her own family. Tactful handling of B's father permits her to make the final decision for the family in most cases despite the father's ill temper and unreasonable behavior.

Junior two years younger than B, is her superior in every way and is by far the favorite all round. He is fond of teasing her to distraction.

At two years of age B was trained in toilet habits. At six years she experienced a long siege of illnesses after which bed wetting returned and has been more or less constant ever since. Scolding has only produced indifference to the habit. Her one refuge is a devoted maternal grandmother whom she visits frequently.

C Diagnosis

- 1 Retarded Intelligence (I Q 88—technically dull)
- 2 Malnutrition (fourteen per cent underweight)
- 3 Facial acne vulgaris (mild)—(additional cause for self-consciousness)
- 4 Emotional insecurity—rivalry of brother and father's indifference

5 Enuresis on basis of habit plus the insecurity
6 Failure in school on basis of retarded intelligence plus a carry-over of her protest against insecurity

D Analysis B's presence on the honor roll up to the sixth grade indicates that more than mere intelligence may boost a candidate to that position in the elementary grades. At that time the work became more difficult, and she lost the security afforded by the high marks. Since then all her energies have been required merely to keep up with the class and her logical reaction was one of dislike and resentment. The enuresis may have begun quite accidentally during the fluid therapy associated with the exanthematous fevers at six years of age or it may have been a subconscious emotional manipulation of the natural desire (reminiscent of cradle days) to continue to enjoy and prolong the extra devotion and attention which she received during her protracted illness (Freud). Repetition (habit) and faulty discipline (scolding punishment, reminders) soon fixed it into what she had come to believe was an incurable habit—so that she carried a rubber sheet with her whenever she slept away from home.

The association with younger children and dolls merely afforded less competition and allowed her

to continue as the "big boss" of the group (compensatory, in much the same spirit that children display when they want to be teacher when playing at school)

E Comment B was invited to keep a record of her dry nights on a private calendar, and was agreeably surprised to find that she had had nine dry nights, the last four of which were in succession, by the end of her first month. Restriction of fluids after six P.M., omission of condiments, and other exciting factors (radio, games, books), and the co-operation of the family in avoiding all mention of the habit, including reduction of Junior's teasing, were materially helpful. B was duly praised and for her effort was awarded a pass to the theatre (furnished through the courtesy of local cinema houses). She was told that such a record proved that her urinary system was normal, that enuresis was a mere habit like nail-biting, and that it could be controlled with practice. An attractive calendar, mounted on a piece of leathercraft (done by one of our rehabilitated juvenile delinquents) was presented to her with instructions to note how many more D's (representing dry nights) she could record by the next visit. No reward was promised, but when deserved, there was nearly always some game, book, or theatre pass to give suitable encouragement. During the next seven months she succeeded in recording 20 to 30 D's per month, according to circumstances at home. Thus, when report cards were poor, or disappointments were frequent the D's would fall off. Despite the father's neglect to answer our letters, or to visit us, his ultimate cooperation was apparent and the mother reported that he looked forward to receiving our reports. Soon B began to take renewed interest in her dancing, in which she was talented, and to work harder at school. Simultaneous treatment by family physician for acne and malnutrition was successful.

Enuresis recurs now only sporadically (once in eight to twelve weeks). B, who is really attractive, is becoming increasingly popular with her own set, and, despite her limited intelligence, is going to graduate from high school.

Hers is an unusually good adjustment to an unfavorable environmental influence, for enuresis is one of the most difficult symptoms of insecurity that the child guidance clinics are called upon to treat.*

CASE 3 T (S H No 13064), aged fifteen years, junior in high school

A Complaint

- 1 Stuttering (Stammering)—duration eight years
- 2 Request for vocational guidance

B Relevant Data An only child—difficult labor—very sensitive. When the mother suggested castor oil recently for abdominal pains, he told her she "must not be so personal." Cried, and refused to recite in school through fear of ridicule, result—low marks.

C Diagnosis

- 1 Stuttering dysarthria
- 2 Introverted adolescent
- 3 Superior intelligence (I Q 121)

D Analysis T talked too rapidly, and therefore stumbled over his words. An attractive, tall boy, he was self-conscious about his size, and also about his defective speech, which had begun innocently enough shortly after a boy playmate who stuttered badly had moved to a distant neighborhood.

E Comment T's natural bent for mechanical things was encouraged. He and the psychiatrist spent

many hours in each other's workshops, exchanging ideas, and assistance. From a few simple lessons in amateur photography T has built up, during the past three years, a demand for his photographs by local newspapers, and also makes enlargements, and creditable lantern slides for lecturers. The technique for correction of his defective speech is fairly simple, and may be embodied briefly into the following rules which have proved to be effective clinically in most of our cases*.

F Rules for Correction of Stammering (or Stuttering)

1 Always speak very slowly. Precept on the part of teachers and members of the family is more important in this connection than reminders, scoldings, or forcing the stutterer to repeat his broken words.

2 Rounding of the lips into exaggerated pronunciation of the letters, as though speaking through a megaphone, helps to overcome a very common source of dysarthria—viz, the habit, when speaking, of using only the tongue and mandible, as do ventriloquists. Part of this is habitual (often in imitation of elders), and part of it is caused by fear. Speaking without the use of (or with minimal use of) lips or mandible produces a stilted and flat, fallible vocalization which inevitably invites trouble with such consonants as B, F, M, P, Q, V, W, and Y, all of which properly require the use of lips and teeth, as well as tongue and mandible.

3 Consonant formation, for stammerers, comes more easily when the troublesome letter is not the first letter of the word. Thus "B" in "ambition" usually offers considerably less trouble than "B" in "bandit." Therefore, one way to uncondition the offending letter is to practice with long lists of words containing the desired letter in the middle, or at the end, e.g., "oboe" and "hubbub."

4 The element of fear produces tension. There is more tension in the respiratory system at the end of inspiration than at the end of expiration, consequently, stammerers are advised to exhale forcibly before and during speaking. (The counsel to whistle before speaking has the same respiratory as well as psychological effect, but is too audible to be suitable for permanent reeducation.)

5 Often an inaudible aspirant "h" before offending vowels, and before such consonants as "t", "f", "m", "n", "r", "s", "w" and "x", facilitates their pronunciation without stammering, and serves to boost the stutterer's self-confidence. Thus, "h after" (hafter), "h empty" (hempty), and the practice of the letters 'h-ei, h-em, h-en, h-ar, h-es, h-ex, h-oo-w' and the vowels 'hay, he, hi, ho, and hee-oo (hn)'—still rounding and exaggerating the use of the lips—are valuable exercises.

6 Practice lists of selected words—if necessary, omitting the offending initial letter at first until repetition and confidence permit its inclusion—are valuable. Thus, "ord, omen, -ife, and -eight", later adding the "w" with an inaudible "h", thus, "hoo-w-ord", "hoo-w-oman", "hoo-w-ife", the "hoo-w" being practically inaudible, whispered, and formed largely by an expiration and a rounding of the lips as in saying the word "who", softly blowing out the vowel.

7 In obstinate cases, entire words, rather than mere letters on which the patient stammers must be analyzed for pertinent associations before the difficulty can be overcome. The habit of forgetting names, dates or experiences, with impersonal or unpleasant associations, is a familiar demonstration of this mechanism. (Freud's "Psychopathology of Everyday Life".)

*A detailed report on the treatment of fifty cases of enuresis at the Springfield Child Guidance Clinic since 1931 is in preparation.

*A detailed report on the treatment of defective speech as carried out at the Springfield Child Guidance Clinic is in progress.

Only a little practice with a few cases of defective speech is needed to give the educator a valuable tool with which to help these unfortunate people.

T's coöperation and conscientious practicing have long since overcome his stuttering, although at times he still speaks too rapidly. His personality has blossomed materially and he plans to enter college as soon as his financial status permits it. He is at present a successful salesman of photographic supplies.

VIII SUMMARY

1 Biblical and other early literature give evidence that there is little that is new in the modern doctrines of mental hygiene. (Section I)

2 The development of enlightened psychiatry and the work of the National Committee for Mental Hygiene in popularizing the newer attitudes toward the patient who is mentally ill is sketched. (Section II)

3 The importance of the movement is evidenced by statistical data. The enviable position occupied by the family physician is not entirely neglected by him, and he does much along prophylactic lines in the field of organic disease. (Section III)

4 Less than two per cent of the physicians of the United States and five per cent of the nurses are burdened with the care of fully fifty per cent of the sick population of the country, the bed cases alone of which number close to one million people. (Section IV)

5 The problems of mental hygiene are conveniently classified and references to standard authorities on specific phases of psychiatry, sociology, psychology and education, are given. (Section V)

6 Lowrey's classification of etiological factors is presented in Section VI.

7 Essentials of treatment are followed by a brief résumé of three important and troublesome clinical cases: Incurability, enuresis and stammering. (Section VII)

IX. COMMENT

The author is not unmindful of the very large percentage of psychoneurotic patients who remain incurable for the sufficient reason that no mortal healer is able to offer them better substitutes for the unbearable realities from which they seek to escape. The usual avenues of sublimation may be totally inadequate to compensate the unhappy sufferer for the grim realities of rejection, insecurity, disability and poverty. The ranks of psychopathic addicts claim many of this class for chronic 'neurotics', alcoholics, narcotic addicts, and other social, moral and legal transgressors for there are many people who are unsuited by native intelligence, ability and training to assume more than a very limited degree of responsibility, independence, and maturity. But, as in the realms of tuberculosis and malignancies, so too with disordered personalities, our only hope is in early diagnosis

and intensive therapeutic efforts. To help these people to find their natural level in order that they may better be enabled to maintain a happy balance in our complex civilization is one of the aims of mental hygiene.

UROLOGICAL COMPLICATIONS IN GENERAL SURGERY*

BY GEORGE GILBERT SMITH, M D †

A COMPLETE list of urological complications in general surgery would be beyond my power to present and beyond your endurance to hear. It is my intention rather to select for comment certain complications which have occurred in my own experience and to describe them in sufficient detail to give you a definite picture of the particular situation.

Urological complications may be divided into three classes: those due to errors of diagnosis, those due to errors of technic, and those which we may consider as more or less unavoidable complications.

Complications due to errors of diagnosis In considering as complications those urologic conditions which existed before operation, which were not recognized as the primary cause of the patient's symptoms, and which still existed after the operation had been carried out, I may be stretching the meaning of the term "complications" somewhat unduly. These conditions most certainly do cause diagnostic confusion and unless they are remedied by appropriate treatment, they continue to persist after operation as definite urological complications. Almost without exception, these conditions may be diagnosed by appropriate measures; the error lies in arriving at a diagnosis without having employed those methods of investigation which will lead to a proper solution of the problem.

A paragraph borrowed from an article written in 1911 by Maurice Richardson⁴ expresses the situation. "We all know, but we do not always realize the fact, that we overlook pathological conditions easy of diagnosis because we do not happen to think of them. How many times, for example, have I been groping about for a diagnosis, as bewildered as one lost in a fog at sea, but at the first sign of a fog bell knowing his exact bearings, so in the bewilderments of diagnosis I have felt reassurance the minute the right but overlooked possibility has been suggested. One pounces upon the diagnosis—every symptom in the history and physical examination will fit into and prove that diagnosis."

There is real danger of mistaking lesions of the upper urinary tract for intra-abdominal disease. W. E. Stevens⁵, in an article on The Upper Urinary Tract and the Adjacent Organs, dwells at length on the possible errors in diagnosis and shows how easily one may be misled by symptoms. For example, he refers to the statement made by Bumpus and Thompson that in a series of 1001 ureteral calculi, the pain was

entirely epigastric in 162. In these patients, the diagnosis of peptic ulcer had been made in seventeen, of cholecystitis in 145. Lowslev and Twinem, also quoted by Stevens, in a review of eighty-four urological cases, found that thirty-nine of these patients had previously undergone some major surgical operation without relief of symptoms. Thirty-one had had the appendix removed. Hugh Cabot¹ in 1915 reported that in a series of 153 cases of stone in the kidney and ureter at the Massachusetts General Hospital twenty-six abdominal operations had been done without relief of symptoms "which were clearly due to the overlooked calculus in kidney or ureter." The appendix was removed in ten cases.

These figures of Cabot's represented the situation at a time when urological diagnosis was less well developed than it is now, and when the urologist was consulted far less frequently. The introduction of intravenous pyelography has no doubt made such errors more infrequent, although it should be borne in mind that unless intravenous pyelograms are absolutely clear and unequivocally negative, they should be checked by retrograde pyelography.

In the differential diagnosis of lesions of the upper urinary tract and those of intraperitoneal organs, a mistaken diagnosis of appendicitis is far and away the most common error. Maurice Richardson, in the article quoted earlier in this paper and entitled "The error of overlooking ureteral or renal stone under the diagnosis of appendicitis," emphasizes the advisability of having x-rays in all cases of suspected appendicitis in which the diagnosis is not perfectly clear. Among his cases diagnosed as "chronic appendicitis" there were twenty-two in which ureteral stone was found to be the cause of the symptoms. The principal symptom which Richardson considered to be suggestive of ureteral stone rather than of appendicitis was paroxysmal, intermittent pain without constitutional symptoms. The presence of microscopic blood in the urine, he stated, always called for an x-ray.

To my mind, the chief points in the differential diagnosis of ureteral stone and appendicitis are, in the former, sudden onset of excruciating, colicky pain, the gradual shifting of this pain from the renal area to a lower site, with radiation to the groin, testicle or vulva, and the absence of true abdominal rigidity. Slow, gentle pressure will not evoke muscular spasm. Nausea and vomiting, distention and obstipation may occur with either condition. At times, however, each of these two diseases may be atypical. Ureteral colic may come on gradually, appendiceal pain may develop rapidly. Blood may be found in the urine microscopically if an acute appendix lies in close relation to the ureter. The tenderness

*Read at a Meeting of the Detroit Branch of the American Urological Association in Toledo January 23 1936

†Smith, George Gilbert—Visiting Urologist, Massachusetts General Hospital. For record and address of author see "This Week's Issue," page 700

and pain from a retrocecal appendix, as Goldstein has pointed out, may be most pronounced in the costovertebral region. The most definite signs of appendicitis are, I believe true rigidity of the abdominal muscles, a rising temperature and leucocytosis.

The possibility of mistaking a fecolith in the appendix for a ureteral calculus is not too remote. Stevens mentions such a case, I saw a similar one.

One bitterly cold winter night some three years ago I was asked to go 200 miles into the country to see a patient with a stone in the ureter. I arrived about two in the morning and found a man of thirty-three years who gave this history. Three months previously he had the first attack of pain located just below McBurney's point and nonradiating. He also complained of frequency of urination. He entered the hospital at that time but no definite diagnosis was made. The pain continuing he was readmitted. X-rays showed a smooth oval shadow 3 x 1 centimeters at the lower end of the right sacro-ileac joint. In different films its position appeared to vary considerably. An intravenous pyelogram showed normal renal pelvis and ureters. Although the lower portion of the right ureter was not clearly shown the shadow appeared to lie outside its probable course. Cystoscopy showed a normal bladder, a catheter passed easily to the right kidney. The patient's temperature was 99° his white count 16,000. There was no pus in the urine.

Rectal examination gave no positive findings there was marked spasm on light pressure over McBurney's point. A diagnosis of appendicitis was made the shadow being interpreted as that of a calcified mesenteric gland. The patient was operated upon at once the appendix was short and thick its base coated with a thin layer of fibrin. Impacted in the base, where it joined the cecum was a hard mass the size of a marble, evidently a fecolith. The removal of the appendix with the fecolith left a hole one inch long in the cecum this was closed in two layers and a wick left in the pelvis. Although I expected a fecal fistula would result, the incision healed without complication.

If any question exists as to the causation of pain in the right lower quadrant the urinary tract should be excluded by a satisfactory intravenous pyelogram or a retrograde pyelogram. Plain films alone are insufficient as they do not show nonopaque stones or defects in urinary drainage.

It should be borne in mind that in the early hours of an acute epididymitis the pain may be referred to the lower quadrant of the abdomen on the affected side.

Acute infections of the kidney before pus appears in the urine, may simulate intraperitoneal disease. This is especially true of the coccal infections—renal carbuncle and acute suppurative nephritis—, less true of acute pyelonephritis.

Less acute renal lesions such as stone pyonephrosis, hydronephrosis and tumor may cause symptoms which on superficial examination suggest disease of the gallbladder or stomach. Goldstein says "Many cases of renal infections and renal tumor as well as the largest percent

age of renal ptosis were presented for examination with the symptoms of nausea and vomiting." Cabot in his series of 153 cases of renal and ureteral stone found pain referred to the stomach and accompanied by vomiting in three instances.

Two cases in my experience illustrate this symptom-complex.

D. E. a man of sixty-eight was referred to me because of a mass in the right upper quadrant. His chief complaint was loss of weight and strength for six months he had had a slight constant nausea but had not vomited. Once three or four years previously he had passed blood in his urine. The feature of greatest interest to us is that for the preceding few months he had been under treatment for alleged stomach trouble, although gastric x-rays were negative. At the time the writer saw him he had a mass in the right upper quadrant, a right pyelogram showed complete obliteration of the renal pelvis the kidney which was removed by the transperitoneal approach, contained a renal cell adenocarcinoma. The duodenum was adherent to the kidney so that it had to be peeled off. Although the growth had invaded the perirenal fat it had apparently not involved the pedicle or the juxta-aortic glands. The patient's appetite increased and his nausea was relieved for some months. He died of recurrence two years later.

Mrs. B—a woman of sixty-seven, had suffered from stomach trouble for twenty years. At least once a day she vomited. Eight years ago a gastro-intestinal x-ray study was negative there was a question of stone in the right kidney then. The patient occasionally passed blood in the urine for the past two years she had had an uncomfortable feeling in the right flank. Recent x-rays of the alimentary tract were negative but a definite shadow was seen in the right kidney. Cystoscopic study showed a badly infected and almost functionless right kidney which upon removal demonstrated that the kidney tissue was largely replaced by fibroepithelioma. Following operation the patient's gastric symptoms disappeared.

In addition to those cases in which the symptoms caused by a lesion of the upper urinary tract are ascribed to intraperitoneal pathology, we find all sorts of combinations due to extension of malignant disease from one group of organs to another. Two recent autopsies at the Massachusetts General Hospital illustrate this situation. In one, a cancer apparently originating in a bronchus had invaded the kidney and ureter on the opposite side causing ureteral obstruction and urinary infection. The other had a carcinoma of the descending colon which had invaded the renal pelvis with radial extension into portions of the pyramids and cortex.

Ureteral obstruction with secondary dilatation of the renal pelvis and upper ureter occurs in a large percentage of patients with cancer of the uterine cervix and in certain cases of ovarian cancer.

An excellent paper by Henriksen³ of Johns Hopkins summarizes some recent articles on this complication. He quotes Faerber who found in 150 patients dying of cancer of the cervix ure-

teral involvement in eighty-four cases (56 per cent), while in 108 cases (72 per cent) the kidneys showed damage. Bilateral hydronephrosis was present in fifty-five cases, unilateral in forty cases, pyonephrosis in twenty and pyelitis or pyelonephritis in nineteen. Shields Warren⁸ found renal involvement to be the cause of death in one third of the cases autopsied by him. Williams noted hydronephrosis in over eighty-five per cent of the patients with the disease who came to postmortem. Kraul considered uremia to be the cause of death in fifty per cent of the cases studied by him.

A case in this group in which the renal condition was the outstanding feature was that of Mrs. M. She was sent to me because of recurring chills and fever and pain in the left flank. Pyelography showed a definite stricture of the left ureter, five centimeters above the bladder. As dilatation of the stricture failed to relieve the patient's symptoms, the left kidney was removed, it showed a definite pyelonephritis. On pelvic examination a soft cystic mass, thought to be an ovarian cyst, was felt in the left side of the pelvis. After her nephrectomy, the patient's condition improved and she went away for the summer. Upon her return, she complained of abdominal pain and loss of weight and strength, pelvic examination showed the mass to have increased markedly, there was free fluid in the abdomen. She was operated upon and extensive malignant disease primary either in the left ovary or in the uterus was found. Without much doubt the ureteral stricture had been due to this.

A symptom which would seem unlikely to lead one along false trails, but which occasionally does so, is hematuria in women. Women are not always sure whether the source of bleeding is the genital or the urinary tract. W. E. Stevens mentions a case in which the patient herself thought the blood came from the vagina, whereas it really came from a carcinoma of the bladder. Some years ago I saw a similar case in which an excellent surgeon had done a cauterage because of bleeding thought to be from the uterus. The bleeding continued and was found on cystoscopy to come from a cancer of the bladder.

The coexistence of bladder lesions with carcinoma of the cervix is well recognized but frequently overlooked. Henriksen says, "The appearance of urinary symptoms in patients known to have cervical carcinoma is sufficient indication for a thorough examination of the urinary tract before exposing the patient to either surgical or radiological procedure." Band and Wade have described six definite stages of involvement of the bladder from anterior extension of the tumor: "(1) elevation of the bladder floor, (2) fixation of the bladder floor, (3) circulatory changes, as recognized by congestion or petechial hemorrhages, (4) formation of a transverse ridge, (5 and 6) malignant invasion, displaying its presence in the

form of an ulceration, of hypertrophic nodules or of a vesicovaginal fistula."

The close relationship between other conditions of the female pelvis and urinary symptoms has been well covered by W. E. Stevens.⁷ He states that frequency of urination is the most common urological symptom due to gynecological pathology, in a series of 913 patients referred to the gynecological and to the urological clinics at Stanford University urinary symptoms due solely to pathologic conditions of the generative organs were present in about twenty-five per cent of the gynecological cases, while twenty-two per cent of the urological cases had concomitant gynecological symptoms or pathology. Salpingitis, according to Stevens, is the most common gynecological condition requiring differentiation from pathology in the urinary tract. Pressure from the pregnant uterus or from uterine fibroids may cause disturbance of the bladder function. Cystocele may be responsible for incomplete emptying of the bladder, the cystitis due to infection of this residual urine cannot be cleared up until the underlying cause is removed. Prolapse may cause hydro-ureter and hydronephrosis.

The possible complications in this field of surgery are too numerous to describe, the point is that before operating upon a gynecological condition for relief of urinary symptoms, one should be sure that the cause of these symptoms is not primarily in the urinary tract. Particularly important is the examination of the urethra, for in many women whose urine is perfectly normal the urethra is the *fons et origo mali*.

Diverticulitis of the sigmoid may cause complications in the lower urinary tract. An inflamed diverticulum may adhere to the fundus of the bladder, suppuration ensues and is followed by the formation of a vesico-intestinal fistula. Even without as definite a relationship as this, diverticulitis in the male may be a factor in causing symptoms which appear to be of prostatic origin. Frequency and dysuria suggest the prostate as their cause, whereas it is the colonic irritation which is the trouble. Symptoms are referred to the prostate when that gland is really not at fault.

One could continue indefinitely to catalog those signs and symptoms which lead the diagnostician away from the true origin of the disease. Hyperparathyroidism as the cause of renal stone, malignant deposits in brain, neck, chest or long bones giving the first intimation of a cancer of the kidney, urological manifestations of lymphoblastoma, sacro-iliac strain as the cause of bladder symptoms, and calculi impacted in the lower ureter as the cause of sacro-iliac pain—examples of all those conditions could be given. The urologist should bear in mind the possibility of the coexistence of lesions outside

the urinary tract as much as the general surgeon should consider the likelihood of lesions within it

Complications due to errors of technique In this category we find chiefly injuries to the ureter or to the bladder occurring in the course of a pelvic operation. I have seen a number of instances of this, sometimes occurring during operations by excellent surgeons. Injuries to the ureter consist in ligation, incision of the ureteral wall or complete cutting of the ureter. It seems not unlikely that unilateral ligation of the ureter may occur fairly often, the kidney atrophies without much ado and no one is the wiser.

A year ago I saw a woman who had had an appendectomy after which she had a persistent right pyelitis. Pelvic examination showed an indefinite induration in the right side of the pelvis. Two years before that pyelograms were normal. Five weeks after operation she came under my care. Pyelography showed a definite stricture of the right ureter just below the pelvic brim. At first it was difficult to pass the stricture but once a catheter had been passed, the stricture dilated readily and eventually the pyelitis cleared up. Whether the ureter was accidentally ligated which is hard to believe was compressed by retroperitoneal inflammation or whether the appendix was blamed for symptoms really due to the ureteral stricture, I cannot say.

Some fifteen years ago I saw in one week two women in whom both ureters were ligated during hysterectomy. One was seen four days after operation. She had voided but one ounce of urine. Catheterization of the ureters showed both to be entirely obstructed about five centimeters above the bladder. Bilateral nephrostomy was done at once. Three weeks later both ureters were exposed and found to be constricted to mere fibrous cords. The strictured areas were excised, the ureteral ends cut diagonally and united end to end. Catheters were passed to both kidneys, a procedure which I believe was not necessary. The patient made a good convalescence and nine years later catheters were passed easily to both kidneys. Specimens of urine showed bacteria but only an occasional pus cell. This patient is still living eighteen years after operation. The other patient was not so fortunate. Her uterus had been removed because of cancer. She died of this disease within two years. In her case the ureters were ligated close to the bladder in attempting to restore their patency following a bilateral nephrostomy. I was forced to reimplant them in the bladder. The right anastomosis held but a urinary fistula arising from the left ureter persisted. In another woman hysterectomy was followed by persistent pyelonephritis. Catheterization of the left ureter showed an obstruction at the pelvic brim. Nephrostomy was done followed by an attempt to restore the patency of the ureter. Apparently the latter had been partially divided there was an abscess about the ureter the upper segment was thickened and dilated. The ureter was united by telescoping the smaller lower segment inside the dilated upper segment this restored the ureteral function for a time as was proved by the passage of indigo carmine from the ureteral meatus. The patency of the ureter did not persist catheters could not be made to pass the stricture and nephrectomy was eventually done.

In still another case during a vaginal hysterectomy the right ureter was nicked but not severed. A ureterovaginal fistula persisted, but closed after a

catheter had been passed up the ureter and left in for forty-eight hours.

If such an accident is recognized at the time of the operation, a catheter should be left in the ureter and adequate drainage for possible leakage provided. A Levin tube may be used, the tip should be passed to the renal pelvis the other end to the bladder. The end in the bladder can be extracted by means of a cystoscopic rongeur forceps. If the ureter is completely severed the operator should immediately reestablish the channel by drawing the upper segment into the lower segment by a suture at two opposing points of the cut end, three fine catgut sutures should be placed to attach the tip of the lower segment to the wall of the upper segment. If it is feared that the ureteral lumen will be temporarily obstructed a small catheter may be passed to the renal pelvis through an incision in the ureter above the anastomosis. Sisk² advises end-to-end suture about an indwelling ureteral catheter.

Accidental incision of the bladder wall during a pelvic operation should be closed by two rows of infolding sutures, and the bladder drained by a urethral catheter.

Unavoidable complications Without question the most frequent of these is postoperative retention. In women more than in men this complication is likely to result in a period of urinary infection the bladder first then one or both renal pelves being involved. After ten days or two weeks the process quiets down leaving the patient with an irritable urethra or a chronic bacilluria. I doubt if catheterization is or need be, responsible for this infection. The fault lies in too little not too much use of the catheter. Patients are allowed to become overdistended, the bladder suddenly emptied of thirty or forty ounces of urine becomes congested and vulnerable to the few bacteria which are unavoidably introduced. If nurses were taught to spend less time scrubbing their hands before catheterization and more time in irrigating the bladder after catheterization fewer complications would arise. Any non-irritating sterile solution such as potassium permanganate 1-8000 may be used. The patient should be given methenamine by mouth in fifteen grain doses every eight hours, or intravenous methenamine grains thirty one, every twelve hours.

In male patients, unless the retention seems likely to be temporary it is often better to fasten a catheter in the urethra than to practice intermittent catheterization. This is particularly true in patients who have been subjected to removal of the rectum the wide dissection of the pelvis may interfere with nerve fibers going to the sacral plexus and produce a bladder paralysis which will last sometimes for weeks. In these cases cystoscopy shows a gaping internal sphincter similar to that seen in tabetics. As many of the patients in whom removal of the rectum

is done are in the prostatic age, there is always the possibility that prostatic hypertrophy is at least partially responsible for the retention. If this is the case, the prostate may be removed either suprapubically, perineally or by transurethral resection. In view of the fact that the patient has been through a severe operation, the last method would seem to be particularly appropriate.

For the orthopedic surgeon, an interesting complication is the formation of renal calculi in patients who have been confined to bed for long periods with ununited fractures. These patients are sometimes given a diet rich in calcium to promote union, the excess of calcium in the blood from this source and from the absorption of lime from the skeleton which goes on during periods of inactivity is largely responsible for the formation of urinary calculi. Such a case occurred at the Massachusetts General Hospital and was reported by Barney.

The patient was under treatment for ununited fracture of the femur and had been taking two quarts of milk a day, a diet rich in calcium and calcium lactate. Bilateral renal calculi were discovered after the patient had been under treatment for six months. Twelve days after x-rays showed these stones the left kidney was operated upon. No stones were found. The patient then said that since being x-rayed he had passed quantities of sand in his urine. He was followed for six months, at the end of which x-rays showed no shadows in either kidney. This unfortunate complication does not occur very often, but the possibility should be borne in mind. The administration of vitamin A in such cases and acidification of the urine may be of value as a preventive measure.

Another complication which we may classify as unavoidable is the formation of vesicovaginal fistula during parturition. Since these fistulae are usually linear tears through relatively healthy tissue, with no loss of substance, there should be a good chance of closing them at the first attempt. Closure becomes more difficult with each successive operation. The best time to operate upon these fistulae would seem to be as early as the patient's general condition will permit, perhaps within two weeks after delivery. The most severe tear that I have seen ripped the bladder neck between the urethra and the right side of the pubic arch, allowing the urethra to fall over to the left side and leaving a wide opening into the bladder. This tear was repaired three weeks after delivery and healed by first intention.

The most difficult fistulae to repair are those

resulting from slough caused by radium used in the treatment of cervical carcinoma. In these patients the tissues about the edge of the fistula are so devitalized that their healing power is greatly impaired, the loss of tissue and the fixation of the bladder base are other factors which prevent approximation of the edges of the fistula. In these cases ureteroenterostomy is the only solution.

Radium burns of the bladder following treatment of cervical cancer which are not severe enough to cause fistulae may be responsible for great suffering. The most stubborn cases are those which develop years after the application of radium, in a woman whom I have been seeing the ulceration developed nine years afterwards. The process, according to Dean, is due to an endarteritis of the vessels in the bladder base, some factor, probably infection, supervenes and the mucosa of the bladder base, its resistance lowered by impoverished blood supply, breaks down into a sloughing area upon which lime salts are deposited.

These are but a few of the urologic complications which may be encountered by the general surgeon, the orthopedist or the obstetrician. Each one of these complications deserves more discussion than our time will permit, but I hope that the subject has been presented with sufficient fullness to illustrate the point that I wish to make. That point is, that no specialty is complete in itself, that every specialist must first of all be a well-trained diagnostician, cognizant of the general principles of medicine and surgery, that he must be ready to ask for help from specialists in other branches whenever he encounters a problem not limited to his own field.

NEW HAMPSHIRE MEDICAL SOCIETY

FOREIGN BODIES IN THE AIR AND FOOD PASSAGES*

BY JOHN A. COYLE, M.D.† AND LESLIE K. SYCAMORE, M.D.‡

ENDOSCOPY is a general term covering inspection of the larynx, trachea, bronchi, esophagus and any cavity of the body by the endoscope. In this paper we will attempt to cover some of the most important points dealing with foreign bodies in the bronchial tree and esophagus. They are removed by the procedures known in medicine as bronchoscopy and esophagoscopy. This is a specialized branch of surgery adapted to the strictest examination of the tracheobronchial tree and esophagus for the purpose of extracting foreign bodies, diagnosis and treatment of diseases of the air and food passages. These examinations are carried out with a rigid tube that has special sources of illumination located at either or both ends of the tube.

In 1804 Bozzini¹ invented 'The Light Conductor' an apparatus for looking into the various cavities of the body. His efforts were considered to be those of a charlatan and quickly met with disapproval. Twenty five years later Babington² devised a simple mechanism called a 'glottiscope'. This consisted of a mirror and tongue depressor combined, but its use was limited to a small number of cases and it was never accepted as an important aid in medicine. In the year 1854 Manuel Garcia³ a musician became interested in the larynx. With the aid of two mirrors he examined his own larynx. Eleven years later he read a paper before the Royal Society of London under the title 'Physiological Observations on the Human Voice'. Thrack and Czerniak⁴ popularized the use of laryngeal mirrors.

In 1890 A. Kirstein⁵ of Berlin devised a method of direct laryngoscopy which he called 'autoscopy'. In 1897 he described tracheoscopy by inspection through the glottis exposed to view by his method. That same year Gustav Killian⁶ demonstrated the feasibility of passing straight and rigid tubes through the glottis into the tracheobronchial tree. He also showed that these tubes could be used for inspection when illuminated by the Kirstein headlamp, a specialized arrangement attached to a headband. In 1897 he removed a foreign body from the bronchus of a living child.

In 1898 the first bronchoscopy worthy of name was done in this country by Algernon Coobidge

Jr.⁷ at the Massachusetts General Hospital using an open urethroscope a head mirror and reflected sunlight. Through an already existing tracheotomy fistula he removed a piece of hard rubber cannula from the right bronchus of a man, aged twenty two.

By July, 1902 twenty cases had been reported in which foreign bodies had been removed by bronchoscopy. Euthorn devised an esophagoscope the same year that is similar to the one in common use in this country today.

The search for foreign bodies in cases where they were or were not present led to the discovery of lesions existing in the air and food passages and the consequent application of medicaments. Thus the search for foreign bodies was a forerunner of diagnosis and therapeutic measures previously not in use. In one of the largest clinics in the world specializing in this field of work it has been estimated that only two per cent of their work is for foreign body extraction while the remaining ninety eight per cent is comprised of diagnosing existing lesions and the treatment of them.

Since the time of Killian the instruments and technique have been so tremendously improved that this branch has won an important place in modern surgery. Before proceeding farther, mention should be made of Dr. Chevalier Jackson⁸ of Philadelphia who has done more in connection with all branches of this work than any other person or persons. His efforts have been tireless in presenting to the profession his profound knowledge and observations obtained from thirty years of practice along this line as well as devising some of the most efficient apparatus for this type of work.

If bronchoscopy and esophagoscopy were more widely used many unsuspected and obscure lung and esophageal troubles would be revealed, a large percentage of which respond favorably to treatment.

In order to obtain good results one must undergo specialized training and have experience. One must work in close collaboration with the general physician and an x-ray specialist, as well as have the cooperation of carefully trained assistants. Teamwork is essential for successful results. Ninety-eight per cent of cases of foreign bodies are reported as cures.

All bronchoscopes and esophagoscopes of practical value have been straight and rigid tubes. To be otherwise would defeat the purpose of observation of existing lesions. Most of the work is done at the end of a long tube

*Read at the Annual Meeting of the New Hampshire Medical Society at Manchester May 8, 1936.

and in a narrow passage, necessitating monocular vision. The chief differences in the various forms of instruments have been in the methods of illumination. Dr. Jackson's instruments, which I believe are most widely used in this country, have distal illumination, while the Bruning instruments used in Europe have proximal illumination. This is not the place for a discussion of relative merits of the two types. For removal of particular foreign bodies, many specialized types of forceps have been devised, and one must constantly bear in mind the possibility of damage by instruments and by the withdrawal of a foreign body.

We are interested today primarily in cases of known or suspected foreign bodies in the air or food passages, but endoscopy is by no means limited to this type of case. According to C. H. Thomas⁶ the indications for bronchoscopy are as follows: Foreign bodies in the lung, bronchiectasis, persistent purulent expectoration, lung abscess, tracheal or bronchial obstruction, unexplained dyspnea, unexplained cough, massive lung collapse, lung conditions simulating chronic tuberculosis without demonstrable tuberculous infection. To this list Dr. Chevalier Jackson⁷ adds that the "asthmoid wheeze" heard at the mouth instead of over the chest wall, and the typical signs of obstructive emphysema are nearly always pathognomonic of an endobronchial foreign body.

Thomas⁶ lists the contraindications as follows: aneurysm, high blood pressure, advanced cardiac disease, chronic nephritis, active pulmonary tuberculosis and a moribund patient.

The indications for esophagoscopy are as follows: The presence or suspected presence of a foreign body, impaired laryngeal motility except in cases of aneurysm, and any abnormal sensation in swallowing. The contraindications are more or less the same as for bronchoscopy.

Usually neither bronchoscopy nor esophagoscopy is an emergency procedure, and it is extremely essential to obtain a careful history, paying particular attention to minute details. Lyman Richards⁸ states that oftentimes a history of aspiration is available, but must be obtained from the parents of a child. Unless the physician, having the possibility in mind, questions them closely a valuable clue may be lost. A general physical check-up should be completed with appropriate laboratory tests. Upper respiratory passages should be examined, with special attention given to dental sepsis, and corrected when possible. An x-ray should be taken in every case of suspected foreign body, even though the suspected substance is not dense enough to cast a shadow, as lesions may be revealed by the x-ray indicating the location of a foreign body which itself does not appear. For localization, plates from various angles are

oftentimes necessary, and fluoroscopy with barium is often indispensable for determination of esophageal conditions and then location. When time permits, the patient should be prepared as for any operation. It must be remembered that the patient is more or less immune to organisms that he himself harbors, yet infections introduced may be extremely virulent, so surgical asepsis is to be desired. In general, most of our cases have been done with avertin anesthesia. This does not seem to deaden the cough reflex which is a very essential factor for the prevention of complications. During the narcosis with avertin there is usually no increase in bronchial or salivary secretions. Our cases experienced no nausea or vomiting and the patients usually retain no recollection of events. I might add that opiates are not used in conjunction with the anesthesia or afterwards, because of the desirability of retaining the cough reflex to aid the clearing of the passages.

The most important part of the introduction of these instruments is the position of the patient, who may be sitting or recumbent, but in either case the position of the head and neck is relatively the same, and a trained assistant to hold the head is necessary. In all of this work, mouth, pharynx, esophagus or trachea must be brought into a straight line, not by crowding the tube but by proper position. This is obtained by extension of the head at the occipitoatlantal joint and not the whole neck extended. One may enter the esophagus instead of the larynx. This error can be detected by failure to receive the tracheal blast and by the appearance of the walls of the passage. Roughness is to be avoided and the tube should not be extended beyond the area of vision. By using a suction apparatus or swabs, the passages are freed of secretions.

The initial symptoms of a foreign body in the tracheobronchial tree are usually choking, gagging, coughing, wheezing, hoarseness, dyspnea, cyanosis and cloupiness, or symptoms may be entirely lacking. There may be a quiescent period followed by pronounced respiratory symptoms plus general toxic effects. Physical signs in the chest change with bronchial movements and the shifting of secretions. In a case of obscure bronchitis, one should think of a foreign body. Nonobstructive metal objects afford few symptoms and few signs for weeks or months, then later show evidence of suppuration. Vegetable matter such as peas, peanuts, beans, etc., cause violent reactions at once such as toxemia, cough and irregular fever. The character of the foreign body often changes. If metal it may become partially oxidized, if vegetable matter it may be broken into pieces. Foreign bodies usually produce early changes in the mucosa, such as edema, granulations and increased mu-

concretion. Metal foreign bodies are usually easily detected by x ray plates. Occasionally however they may be hidden by lung shadows or are themselves too small to cast a satisfactory shadow. Early bronchiectasis due to the presence of a foreign body, is usually cured by bronchoscopic removal of the exciting cause.

Seventy per cent of foreign bodies enter the right bronchus because of its increased diameter and less acute angle of deviation from the line of the trachea. Of course the position of the patient during inspiration and pulmonary movements may influence the ultimate resting place of the foreign body.

Therapeutic measures of shaking the patient by the heels with the head lowered may be successful in the first few minutes before the foreign body has passed the glottis.

The principal symptoms of esophageal for-
eign bodies are difficulty or discomfort in swallowing. The localization of pain is very definite, as patients not infrequently refer the sensation to a point at some distance from the site where the foreign body is lodged. Small bones are especially liable to be lodged in or about the tonsils, or in the pharyngeal wall. Complete esophageal obstruction is usually due to a large bolus of meat. A. J. Wright, in the *Journal of Laryngology and Otology*, March 1934, writes that "pain on swallowing, or its increase after twenty four hours or so, makes the presence of a foreign body extremely possible." In neglected cases, esophageal perforations are the rule, leading to disastrous results. Cummings¹⁰ noted that about seventy per cent of foreign bodies found in the adult esophagus were in cases wearing dentures. These people have difficulty with bones especially and often swallow them.

A large percentage of foreign bodies in the esophagus are demonstrable either by the x ray plate, fluoroscopy or fluoroscopy in conjunction with the use of barium.

The blind method of passing esophageal bougies or probes attempting to dislodge foreign bodies or to dilate esophageal constrictions is only mentioned to be condemned.

One must not lose sight of the fact that pre-existing esophageal lesions may be first evidenced by the lodgment of a foreign body at the constriction caused by the lesion.

Most large esophageal foreign bodies are caught in the region of the cricopharyngeus muscle.

I would like to review briefly a few of the cases that we have had illustrating some of the points that have been mentioned.

(Slides were shown.)

CASE 1. A. J. aged three years, was brought to the hospital August 2 1933 because of difficulty in breathing supposedly of five days duration. Fur-

ther questioning brought out the fact that this symptom had been present for several months. Temperature 104° pulse 120 respirations 25 on admission. Examination of the chest showed breath sounds absent throughout the lower left chest. Dr. Stewart thought of foreign body possibility and advised x ray of chest.

(Slide shown.)

Foreign body was removed August 4 1933. The patient had more or less of a stormy course and was taken from hospital against advice August 12 1933. Condition improved. August 25 1933 he was brought in for a check up. Admission was advised because of varying temperatures. Discharged September 6 1933 greatly improved. Recent reports indicate that he is well.

(Slide shown.)

CASE 2. E. C. aged six years. Chief complaint wheezing. One week previously while playing with a paper clip in mouth he seemed to have swallowed it. He was taken to a doctor who told the parents not to worry that it would pass through the intestinal tract, or to wait until something developed as a result. At the time of the accident there were considerable coughing, dyspnea, and cyanosis for a few minutes. His mother became worried and brought him to the hospital for a chest x ray. On admission November 17 1933 temperature 100° pulse 100 respirations 20. The child did not seem acutely ill.

(Slide shown.)

Foreign body was removed November 17 1933. The patient was discharged November 20 1933.

CASE 3. M. D., aged three years and 8 months brought to the hospital and admitted June 24 1933. Four weeks previously while quarreling with her sister aspirated a peanut. Some coughing at the time. One week later began to wheeze. A nurse diagnosed asthma. No dyspnea or cyanosis. Three days before admission developed what seemed to be a cold. Temperature 98° pulse 130 respiration 25.

(Slide shown.)

Foreign body half a peanut, removed June 25 1933. The patient was discharged July 6 1933.

(Slide shown.)

CASE 4. H. B., aged sixty-one years. Admitted August 21 1933 complaining of discomfort and difficulty swallowing. Onset while eating chicken.

(Slide shown.)

Foreign body chicken bone removed the same day. Discharged the following day.

CASE 5. B. D., aged fifty-seven. Admitted February 10 1934. Complaints choking off and on past three years. Loss of 1½ lbs weight during winter. Day before admission was unable to get solid food down, because of sudden obstruction. Considerable distress in chest such as pain and pressure. Small amount of liquid would pass at times. Physical examination and Wassermann negative.

(Slide shown.)

February 14 1934 esophagoscopy examination revealed a large bolus of food lodged in the middle third of the esophagus. This was removed and a small tumor was seen projecting from the posterior wall. A biopsy taken was reported to be a carcinoma. Deep x ray therapy given. Returned a few days ago for a check up. No symptoms or evidence of obstruction.

CASE 6. H. B. aged seventy years. Admitted April 20 1934. Unable to swallow. Pain in the chest. Twenty four hours previous to admission the patient coughed while eating. Since then, unable to swallow food. Liquids passed down slowly.

(Slide shown.)

A large piece of meat attached to a bone was removed the same day. The patient was discharged the following day.

(Slide shown)

In conclusion I would like to add that foreign bodies left or undiscovered in the lungs or esophagus, will ultimately produce disastrous results, and I hope that we have brought out the necessity of further examination in obscure pulmonary and esophageal conditions.

[Dr Coyle and Dr Sycamore then showed many slides on the screen, both interpolating discussions on the subject of Bronchoscopy]

DISCUSSION

PRESIDENT LORD I will call upon Dr Robert M Deming of Glenciff to discuss the subject of Bronchoscopy

DR ROBERT M DEMING *Mr. President and Members of the Society*—I feel that I can add but little to this interesting talk by Dr Coyle, since he has covered the subject quite thoroughly. My interest in bronchoscopy is from a purely clinical viewpoint, as I am not experienced or interested in the technique of the procedure.

A clinician is interested in bronchoscopy as a means of differentiating various conditions, which may be present in the chest. Chief of these is bronchiectasis a condition much more common than was previously thought, and frequently diagnosed and treated as pulmonary tuberculosis, even in sanatoria.

Bronchoscopy, combined with lipiodol injection and x-ray, should make a diagnosis. It is valuable in detecting and diagnosing chronic nontuberculous lung infections, fibrosis of the lung or silicosis, abscess of the lung for drainage, provided the abscess is not located too far up, for obtaining material for a biopsy to differentiate and definitely diagnose tumors of the lung or bronchi.

One of our patients is now having a bronchoscopy and lipiodol injection to determine whether she has a papilloma of the bronchus with resultant plugging of a bronchus. It is used quite spectacularly in removing foreign bodies. The cardinal indications for diagnostic bronchoscopy are the clinical or x-ray evidences of bronchial obstruction, and in no connection is this more valuable than in early diagnosis of bronchial carcinoma.

The use of the bronchoscope is limited, or should be, to special operators, since the procedure is not carried out without danger of some damage to the trachea and lungs.

When a patient presents a varying amount of non-productive or only moderately productive cough for a long period, occasional hemoptysis in varying amounts from streaking to large hemorrhages, per-

sistently negative sputa, and roentgenograms that are inconclusive, but which give evidence of a difference in density of the lung fields, indicating distention of the upper lobe on the affected side, and as an inequality in the position of the diaphragm best seen in the lateral roentgenogram, it is reasonable to suspect an atelectatic bronchiectasis of the lower lobe. A bronchoscopy with lipiodol injection should then be of the utmost value.

PRESIDENT LORD This paper is now open for discussion, and I know that we are all interested in this business of making inspection of the interior.

DR LOUIS C AOKR There are three points that I want to mention. One of them is rather interesting historically. I have never seen it mentioned in any published discussion of bronchoscopy.

In the late eighties,—I think it was about 1888,—Dr Rushmore, Professor of surgery at the Long Island College Hospital, had the following case.

A prominent clergyman of Brooklyn was playing with his children and insufflated a small cork which lodged in a bronchus, with the usual inflammatory results. He came into Dr Rushmore's service in the hospitals and various measures were tried. Dr Rushmore had the idea of extracting with a corkscrew. After various attempts at manufacture, a flexible metal tube was constructed with a slit to permit respiration in the opposite lung. This was inserted into the bronchus and into it was run a long flexible corkscrew. That the cork was actually reached was proved by the fact that a piece of cork was broken off and recovered. However the patient died of pneumonia, or perhaps atelectasis. Later the professor exhibited the tube and cork to his medical students of whom I was one.

Another matter that I wish to mention is the work of Dr Stitt of Cincinnati over a considerable length of time while I was stationed in the Cincinnati Office of the Veterans' Bureau. No doubt most of you have seen his reports but I wish to verify the fact of his very satisfactory results in lung irrigation with a hypertonic salt solution. I saw several severe cases of bronchiectasis,—some in very old people,—tremendously relieved. One man told me that he had not been able to go to bed for two years but, after a few treatments, he was able to get several hours' sleep at a time in bed. I wish some of the bronchoscopists here in New England would make use of the method. We have a good many cases of bronchiectasis among the Veterans.

One other observation. We have had in the Hospital at Rutland Heights, for some time, a patient with evidence of pulmonary tuberculosis. His chief trouble, however, has been sudden severe attacks of vomiting during eating with severe pain in his chest. X-rays were made without showing anything until he had a typical severe spasm of the esophagus just as he was swallowing the barium. It showed up wonderfully.

PRESIDENT LORD Is there further discussion on this paper?

DR H O SMITH In the town adjoining mine, a schoolboy in good health, aged ten years, began to develop a slight cough and to lose weight. The tentative diagnosis was incipient tuberculosis. Finally, he developed an acute process in the lung, with high fever, pain, profuse expectoration. I made a diagnosis of lung abscess. An x-ray was taken and it was found that he had in one of the small bronchi, a carpet tack. The child was taken to the Children's Hospital. Dr Richards removed the tack under general anesthesia. The boy went to his home and the cough gradually ceased. He put on weight, and now is a typical, healthy, country boy.

PRESIDENT LORD Is there any further discussion?

Dr. FRANK N. ROGERS, Manchester X-ray does not always help although I agree with Dr. Smith that x-ray pictures should be taken of all suspected cases of tuberculosis and cases of foreign bodies in the larynx. Peanuts will not show up in x-ray. The history of such a case is about the only thing we can go by.

I had a case some years ago of peanut bronchitis which ended fatally although the child lived for a long time after having the peanut removed but due to the traumatism of getting the peanut out the child had to wear a tube.

It is a bad habit for a young baby or a young child to eat peanuts. Peanut butter is all right but peanuts themselves are dangerous.

Nut bars are always dangerous to the very small child. The package of popcorn contains a prize and usually a little metal figure, just about the size that would enter the larynx. I personally wrote to the manufacturers of these articles and warned them against using these prizes.

Dr. RICHARD W. ROBINSON, Mr. President and Gentlemen—I won't take but a minute of your time. The gentlemen who have been talking about this subject have been speaking of bodies that are distinctly foreign that come from the outside.

A little incident that occurred a few days ago I think is perhaps of some importance so I will mention it.

A thirteen months old baby developed an acute lung condition and this was diagnosed by x-ray as a lung abscess. There were several days of illness when finally the child coughed up a little piece of material brownish in color that looked like half a bean which on observation under the microscope and from chemical test proved to be a solid milk curd that the youngster had evidently inhaled after vomiting. I wonder if this sort of accident is not quite frequent and whether it might not account for some of the acute lung conditions of infancy.

PRESIDENT LORD If there are no further remarks, I will ask Dr. Coyle to close the discussion.

Dr. JOHN A. COYLE, Mr. President and Gentlemen of the Society—We attempted to cover briefly only some of the work on foreign bodies. Sometime perhaps, we may present treatment of bronchiectasis and give some credit to individuals that have done a great deal of work along this line. I thank you.

PRESIDENT LORD Do you wish to comment Dr. Sycamore?

Dr. SYCAMORE No I have nothing to say.

CARE OF THE NEWBORN*

BY RICHARD W. EUSTIS, M.D.

THE two specialties of obstetrics and pediatrics overlap. The obstetrician is interested in the infant, the fruit of his skill and the mother's labor. His is the task of aiding him into the world and his is the task of resuscitation if the baby fails to breathe spontaneously. The pediatrician's interest is in the baby's immediate condition and in the stored up reserves of fats, minerals and of vitamins on which he is partly dependent for the first months of life. These reserves, in turn, depend upon the health and diet of the mother.

We were taught that the full term fetus had obtained from his mother all that he needed to start life for himself even though in so doing he seriously depleted her reserves. The observation that the newborn infants of anemic mothers were not themselves noticeably anemic seemed to support this theory. More recent reports however have shown that such infants are definitely anemic at the age of three months, and it is evident that because of the maternal lack they were unable to obtain an adequate reserve of iron.

The dentists associate poor development of the first dentition with deficiencies in the maternal diet more than with defective diet during infancy.

If this is true of iron and calcium it is probably true of all the mineral salts.

It is for these reasons that pediatricians urge that the diet of pregnancy should include an abundance of mineral salts and of Vitamins C and D both of which appear to be necessary for the proper metabolism of bones and teeth. The other vitamins are probably present in sufficient amount in any reasonably well balanced diet.

The rise of pediatrics as a specialty focused attention on the newborn infant and the early articles on the care of the newborn emphasized the importance of maintaining a normal body temperature of 99°-100°F and of minimizing the weight loss. These points are less important than we once thought. More recent work has shown that the rectal temperature of a healthy infant is anywhere between 97° and 99°F and that attempts to force the body temperature above 99° are apt to cause indigestion.

In the first few days after birth an infant loses from five to fifteen per cent of his birth weight. This loss is chiefly water and need not

*The fourth in a series of papers presented in the Symposium on Obstetrics at the Annual Meeting of the New Hampshire Medical Society at Manchester May 1, 1935.

†Little, Richard W.—Physician to Children, Medical Service, Massachusetts General Hospital. For record and address of author see "This Week's Issue," page 100.

concern us if in other respects the infant is vigorous and well

We try to practice moderation while waiting for the infant to develop his own powers. He must be kept warm, but not too warm. He must be given fluid enough to prevent dehydration, but not so much that he is uninterested in nursing. Hunger and thirst are the best stimuli for sucking, just as eager sucking is the best galactagogue.

Our usual routine in the care of the newborn is as follows

BATHING

As soon as respiration is well established, the newborn baby is wrapped in warm blankets, placed in a warm room, and left alone for several hours. If his condition is good, he is then given his first bath. With sick infants, this should be postponed even for one or two days. During the bath, the nurse is trained to look the baby over for any abnormalities that may have escaped the doctor's attention at the time of delivery. Following the bath, he is anointed thoroughly with 2 per cent ammoniated mercury and sent to the nursery. We have found it advisable if the temperature is subnormal to admit the infant to the air-conditioned premature nursery for one or two days until his temperature becomes stabilized.

TEMPERATURE OF NURSERY

Most hospital nurseries are too warm. A hot room is necessary only when the infant is exposed, as during the daily oiling. At other times the air temperature should not be over 70°F. Greater heat is apt to mean poor ventilation and a very dry air which causes excessive evaporation from the skin and mucous membranes and increases the risk of respiratory infections. Also, if the baby is too warmly dressed or in too warm a nursery, the moist skin becomes macerated and forms a favorable field for impetigo and furuncles. The ideal nursery is kept at about 70° and has a treatment room attached to it which may be kept at 75° to 80°. If only one room is available, the high temperature should be permitted only during the time the babies are being oiled and weighed.

Overheating of infants is undoubtedly also a frequent cause of indigestion and diarrhea. We have known for a long time that this was the cause of many of the summer diarrheas, but Blackfan's work with air-conditioned nurseries has shown that it may also be a cause of diarrhea at any time of the year.

BREAST FEEDING

The crusade in favor of breast feeding by the public health experts should be applied to individual cases with discretion. It is perfectly

true that for the mass of the population, the death rate is distinctly lower among the breast fed babies. It is also true that breast feeding takes less time, and is easier and cheaper.

Except in the presence of definite contraindications, most mothers can nurse their babies if they want to. If they do not want to, it is a waste of time to struggle with them. However, if after a reasonable trial, the breast milk is insufficient or if the otherwise normal baby is not gaining satisfactorily, it is only common sense to wean. Mixed feeding after the first month does not work out well in practice.

The infant is put to breast after the first twelve hours, and every four hours by the second day. Until the milk comes in, he should not be left at breast for more than a few minutes. The purpose of this preliminary nursing is to give the baby colostrum, to stimulate milk formation, and to get the mother and baby used to each other. This latter factor is particularly important with a first baby.

There is considerable dispute as to whether the infant should be given water, sugar solution, or even a formula from the bottle during this period of two to five days before the milk comes in. On the one hand are the men who are impressed with the dangers of excessive weight loss and dehydration fever. They advise fluid from the bottle for all infants, and some have gone so far as to order definite amounts at definite hours. Dehydration fever has been rare under this treatment, but the proportion of successful nursing has been comparatively low.

The most effective method of minimizing the initial loss of weight is to give the baby normal saline solution containing 5 per cent glucose. This causes fluid retention and a fairly level weight curve on the chart, but we cannot see that an excess of fluid in the tissues is of any real advantage to the baby. After a few infants developed a generalized edema, we abandoned the use of the glucose saline mixture.

When fluid is offered to check weight loss, whether it be water, sugar solution, or a formula, the infants come to breast fairly satisfied, find nursing a hard job, and lie back waiting for food from an easy running bottle. The mothers complain that their babies won't nurse, their breasts are not satisfactorily emptied, and the milk supply gradually diminishes.

At the opposite extreme is a school which says the infant should never be given a bottle until breast feeding is given up. The percentage of successful breast feeding in such cases is higher but there is no doubt that unintelligent application of the rule may cause trouble.

We believe the wisest of the two courses is to start infants on a routine of nothing by mouth except the regular breast feedings. If this regime is followed, it is very necessary to watch their weights daily, the condition of their skins,

their general vitality and their nursing ability. Most infants will come through successfully, but individual cases will need small amounts of water or sugar solution to prevent dehydration. If a formula is necessary to start them gaining, it usually means that nursing will not be successful.

FEEDING INTERVAL

Regularity of feeding has been preached by pediatricians since the beginning of that specialty, and many reasons have been advanced for its necessity, such as the limited gastric capacity and the three hour emptying time of the stomach. Nevertheless, the chief advantage of regularity seems to be that only in this way can the mother plan her time. There is no doubt that when the milk supply is abundant the baby is healthy, and the mother always available as an infant which is nursed whenever it cries for food does just as well as an infant that is fed by the clock. But regularity is always necessary in a hospital and usually at home, and therefore the wisest schedule for the mother is the one with the fewest number of feedings on which the infant does well. We find that a four hour schedule works out successfully in the vast majority of infants. This is true even of premature babies weighing as little as three pounds. There is an occasional infant that will have to be fed every three hours because his stomach will not hold enough to carry him the four hour period. Such cases are recognized because although they go to sleep immediately after each feeding they wake up and cry an hour before the next meal is due.

Most of the milk at a feeding is obtained during the first three or four minutes, but this first milk is comparatively low in butter fat and it is the latter part of the nursing that contains the most cream. This is the reason that the baby is allowed to nurse each breast eight to ten minutes when both breasts are given and fifteen to twenty minutes when one is given. When we are trying to increase the milk supply we give both sides at each feeding, thereby increasing the number of times each breast is stimulated during the twenty four hours. Occasionally it is necessary for a time to give both sides every three hours, but such frequent nursings are likely to cause cracked nipples.

We can suspect an insufficient milk supply by the baby's apparent hunger by his failure to gain and by small scanty stools. The only conclusive proof, however, is to weigh the infant before and after each feeding for twenty four hours. It is not sufficient to weigh after one or two feedings only as the amount obtained at the individual nursings may vary widely although the twenty four hour amount is steady from day to day.

If the baby's condition is reasonably good, we should not be alarmed by his failure to gain during the first ten days or even two weeks and we should not allow the desire of the parents and grandparents to lead us to introduce a formula until it is necessary. Frequently the full milk supply is not established until the mother is about ready to get up and if we have had the courage to wait, we will find that the infant will start gaining.

An overabundant milk supply is not common and is usually only a temporary matter. It is suggested by a gaining but uncomfortable baby with regurgitation and frequent stools and is best handled by shortening the time at breast and giving only one side at a feeding. If the mother is uncomfortable an icebag will check the secretion of milk.

BOTTLE FEEDING

Successful bottle feeding even with the simplest methods in use today demands a certain minimum of intelligence equipment and medical supervision, and unless these are available every effort should be made to keep the baby at breast. But where these conditions can be met there is no doubt that a satisfied gaining bottle-fed infant is happier and more completely nourished than an underfed infant at breast.

When a baby is to be fed from the beginning on a bottle, we wait the customary twelve to twenty four hours until he is rested and hungry, and then offer first one half to one ounce of water or sugar solution and four hours later the first formula. He will probably take from one to two ounces of formula at each feeding; that is, on the usual four hour schedule of six feedings he will take from six to twelve ounces in twenty four hours increasing gradually to three ounces at a feeding or eighteen ounces in twenty four hours.

Fashions in formulae are nowadays very simple but they still leave room for considerable individual choice on the part of the physician. This individuality seems to be mostly on the doctor's part for at the Boston Lying in Hospital the babies have done just as well since we have adopted a stock formula as they did before on various different mixtures.

Our usual formula is now—

Bolled Milk	12 ounces	— 240 calories
Karo	1 ounce	— 120
Water	to 18 ounces	
		360

This supplies 20 calories to the ounce, which is the same as the average breast milk.

The formula can be made equally well with unsweetened evaporated milk using six ounces instead of twelve.

Other sugars can of course be used in place of the Karo. Equivalent amounts are

Cane Sugar	2 level tablespoonfuls
Milk Sugar	3 " "
Dextrimaltose	
No 1 or No 2	4 " "

Eighty-three per cent of the babies at the Boston Lying-in Hospital were breast-fed during 1934. The remainder, even the premature infants, have done well on this stock formula.

One of the chief reasons for this excellent record lies in the nursing staff. The supervisors and head nurses know how to handle babies and are able to impart their art to the constantly changing pupil nurses. To feed an infant skillfully and well, without causing colic or excessive regurgitation, is an art in some ways comparable to that of the animal trainer. The expert nurse shows the same confident approach and handling, the same understanding of expression and of inarticulate sounds. Confidence begets confidence, and nervousness, nervousness, although the apprentice instead of being kicked, clawed or bitten, merely risks being dieneded with vomitus and kept awake by a crying baby.

The care of the newborn infant includes the early recognition and proper handling of the sick infant. Suggestive signs are an unstable temperature, a weak or high-pitched cry, poor color, poor nursing ability, and either lethargy or increased irritability. Such infants, from the nursing standpoint, should be handled as if they were premature, and the doctor should examine them carefully, having in mind the various diseases of the newborn period. Fever is as apt to mean overheating, dehydration, or intracranial hemorrhage, as infection, and infection may be present with a normal temperature. Also, the white blood count in the newborn period may be as high as 20,000 without indicating infection.

Although this is not the time to enter into a discussion of the diseases of the newborn, there are a few points in our handling of some of the conditions that are worth mentioning.

In cases of apnea and cyanosis, we first clear the airway of mucus by suction through a catheter passed into the pharynx, and then give gentle artificial respiration with the infant in the crib. Oxygen and 5 per cent carbon dioxide is administered through a large celluloid cone which covers the whole head and shoulders.

In intracranial hemorrhage, we first treat shock and then give an intravenous transfusion of one to two ounces of citrated whole blood. If the intracranial bleeding has been due to hemorrhagic disease, as it may be without visible bleeding elsewhere, this should stop the bleeding. If, on the other hand, the hemorrhage is from a torn vessel we think the advantage of the increased coagulability of the blood induced by the transfusion more than outweighs the theoretical risk of a slightly raised blood pressure.

Lumbar puncture is performed after the infant has rallied from shock and preferably early in the stage of increased irritability before convulsions develop. Its purpose is twofold, to confirm the diagnosis and to relieve the symptoms of increased intracranial pressure. The fluid is usually either frankly bloody or xanthochromic, according to the amount and location of the bleeding and is under increased pressure. We find manometer readings of the pressure are of some value in deciding the amount of fluid to be withdrawn and in determining the time of the next puncture. One puncture is enough in some cases, others require two or three at intervals of twelve hours to one or two days before symptoms are relieved.

Any external bleeding in the first few days of life which is not immediately controlled by ligation or by simple pressure, is presumptive evidence of hemorrhagic disease, as is also the vomiting of blood, either fresh or black, or the passing of bloody stools. The only exceptions we make are a blood-streaked, mucous discharge from the vagina which in our experience is almost never associated with bleeding elsewhere, and the vomiting of small amounts of blood by an otherwise perfectly healthy baby where the source of the blood can be traced to a crack in the mother's nipple.

Transfusion is the only really effective treatment for hemorrhagic disease of the newborn. Intramuscular injections of whole blood will control some cases, but they are not effective for several hours, probably eight at least, and during this waiting period irreparable damage may be done by internal hemorrhage. I do not believe it is justifiable to waste any time with intramuscular injections of whole blood or of other coagulants unless transfusion is for some reason absolutely impossible.

Between one and two ounces of blood is withdrawn from the vein of one of the parents, mixed with citrate solution, and injected into a scalp vein or one of the jugular veins of the infant. We have not found it necessary during the newborn period to group or match the bloods. This sort of transfusion sounds simple, but is really a fussy, delicate procedure, best done by an interne or recent graduate from a children's hospital. I think it wiser to bring the baby to such a man rather than to try a bungling job myself.

There have been a few cases reported of successful transfusion during the first three days by loosening the umbilical tie and introducing the needle into the open end of an umbilical vein. Although we have never had occasion to try this, I have kept it in mind as a possible method in case of the failure of the more usual routes.

The important point to drive home is that nurses should report at once any bleeding or any sudden pallor which may indicate internal

bleeding and that a transfusion should be performed as soon as possible after the presumptive diagnosis is made. Only in this way can we avoid a high death rate.

Erythroblastosis is a new name given to a previously unrecognized condition which lies part way between the very serious icterus gravis neonatorum and the comparatively mild anemia of the newborn. The suspicions of the obstetrician should be aroused by the golden yellow color of the vernix and by the hypertrophied placenta. Such infants show a progressing anemia with many nucleated red cells indicating that the young cells are being swept into the circulation. They are usually jaundiced and may develop edema and enlargement of the heart. They should be transfused at once and the transfusion should be repeated as often as is needed until blood destruction and blood production are normally balanced, which may be a matter of several weeks.

Thrush is a recurring pest of hospital nurseries. It appears occasionally in spite of the most scrupulous cleanliness of bottles and nipples as well as the most careful wiping off of all overhead surfaces from which dust and spores may fall. We have tried many treatments and our best results have been obtained by painting the tongue and inside of the mouth with a 1 per cent aqueous solution of gentian violet. Two or three applications at daily intervals usually suffice.

Impetigo in the newborn is a very different disease from that appearing in childhood or adults. It is just as annoying and has more serious possibilities. It may be defined as a contagious superficial infection of the skin caused usually primarily by a streptococcus resulting in the formation of thin walled blebs which are very easily ruptured. The resulting denuded area presents an oozing surface and tends to increase in size by peripheral extension. It is very difficult to draw a sharp line between

a mild, simple impetigo in the newborn and the bullous impetigo or pemphigus neonatorum which results in such extensive blistering and denuding of the skin that the death rate is very high.

For the prevention of impetigo we have found the best plan to be a thorough anointment with a 2 per cent ammoniated mercury ointment immediately after the initial bath. Following this the baby is neither bathed with water nor except rarely, anointed again with the mercury ointment during his stay in the hospital. Instead he is oiled daily with a mildly antiseptic neutral blend of vegetable and mineral oils. We do not believe that this oil alone without the preliminary anointment is adequate prophylaxis but with the combination of the two we have distinctly reduced the number and severity of the cases of impetigo.

If an infant develops a characteristic bleb or denuded area he should be rigidly isolated from the rest of the nursery. The most effective treatment seems to be the use of drying lotions and exposure of the affected part under an ordinary electric light bulb. Ointments and strong disinfectants should be avoided. One or two applications of metaphen followed by the frequent sopping on of whiteness and the electric bulb treatment work best in our hands. It is very important to keep the infant cool as heat and perspiration tend to macerate the skin and aid in the spread of the infection.

MISCELLANY

THE APPOINTMENTS OF MR. JAMES A. HAMILTON

Mr. James A. Hamilton, Superintendent of the Mary Hitchcock Hospital of Hanover, N. H., has accepted the position of Superintendent of the Cleveland City Hospital as of July first as well as the position of Professor in the Graduate School of Business at Western Reserve University.

DO YOU KNOW?

"Colds" are not due to cold weather—Eskimos do not have them unless they come in contact with white men.

"Vitamin" means life-carrier.

More than 700,000 different insects have been named and described by scientists.

Most parents are so busy training children in such good habits as eating regularly that they fail to help them form the habit of liking people. Development of this characteristic will often prevent

fussing about food temper tantrums lying disobedience jealousy and many other bad habits which cannot be easily corrected by direct injunction.

Sleep ought to be measured carefully. Different individuals have widely varying needs in the amount of sleep required. Loss of sleep for one or two nights can be made up but habitual loss of sleep will eventually break down the most rugged system.

Thomas Adams said: Prevention is so much better than healing.

A STUDY IN FEIGNED MURDER*

BY JESSE W BATTERSHALL, M D †

THE morbid philosophy of Schopenhauer that contemplates life as a personal attribute and self-murder as the justifiable destruction of it, happily is now discredited as unmoral. Self-killing is condemned by the Church as moral outlawry and by the State as an indefensible yet obviously unpunishable infraction of its law.

Among the noticeable circumstances attending the current economic distress is the appalling increase in deaths by suicide. From a reported total of 459 suicidal deaths in 1925, the Massachusetts records indicate a yearly increase to a high peak of 639 deaths in 1932 with only a minor decrease in the last two years. Banning from present consideration, suicides, impelled by the fanciful and unreal concepts of the seriously disordered mind, and viewing the residuum impartially as the exercise of individual volition, the resultant is not an agreeable one.

The urge to self-murder has its origin in a multitude of circumstances. Humiliation, ripening into profound depression or morbidity after continued deliberation on fancied social or business losses to follow, is a common albeit unhappy cause. Disheartening disappointments following untoward developments in scholastic effort, frustrated plans for social or financial advancement, thwarted hopes or disillusion in love, these and many other circumstances often provoke emotional crises that in turn are the geneses of impulses to destroy life, so, too, of our national business life in these times of stress. Indeed, from the pages of business history we may cull accounts almost without number of gruesome deaths, self-inflicted, and instigated by financial instability and economic distress.

In many of these cases, the self-destruction is plotted with marked premeditation. Plans are made with infinite care. Religious interdictions cast upon the self-killer, the necessity of surrounding his act with the appearance of accident or even death at the hands of an assailant, to the end that religious rites are not denied, and that no stigma should enure to his family. Again, the skeptical eye of the insurer approaches the presentation of a claim for death loss, with an inquisitorial attitude, searching among the attendant circumstances for some fact, however isolated or insignificant it may appear to the untrained observer, by which to

refute a claim of accidental death and its attendant double indemnity relief.

Still other considerations, as variable as the persons themselves, may often lead the suicide to long, deliberate planning. In short, the suicide contemplates his act with a view to the simulation of a real accident, and with a purpose to thwart the exposure of the truth in future inquiries. Upon those charged with official investigation of violent deaths, in the first instance, there must necessarily fall the heavy burden of weighing the revealed facts, to discern the true from the simulated, and to pass with frank impartiality upon the accumulated evidence.

A suicide, remarkable for the nicety of its detailed planning, came to my attention in 1931. The body of Mr. X, a professional man of high standing in a small manufacturing town in southeastern Massachusetts, was found in the early morning, lying on the floor of his garage, in the basement of his home. A passing school boy, glancing through the open garage doors, was attracted by the headlights of an automobile, inadvertently left burning when the machine was parked in the garage. The frightened boy ran home and told of his ghastly discovery and a relative hastily summoning Mrs. X, went with her to the garage, by way of the kitchen stairway which led to the basement, there the inert body of Mr. X was found lying between two parked automobiles, parallel to the running boards of the cars. Neither motor was running. On the floor by the body of Mr. X there was found a bankbook with eight endorsed checks ready for deposit, together with a slip specifying \$400 in cash. No cash accompanied the checks or book, however, and none was found in the vicinity. On the other side of the body, close to the running board of the second car, Mr. X's empty wallet was found and a few papers and a negligible amount of small change lay close by the wallet. Superficial examination of the body revealed a bullet wound with its entrance directly over the cardiac area on the left anterior chest wall with a sharply demarcated area of blackening around the wound. There was also some tattooing noted. The course of the bullet appeared to be upward. The clothing disclosed burning and powder residue. It was evident that the firearm had been discharged at close range. There were no signs of a weapon nearby, and all outward appearances indicated a murder induced by robbery. The premises were minutely searched for approx-

†Battershall Jesse W.—Medical Examiner First Bristol Dis-trict Massachusetts For record and address of author see This Week's Issue page 700

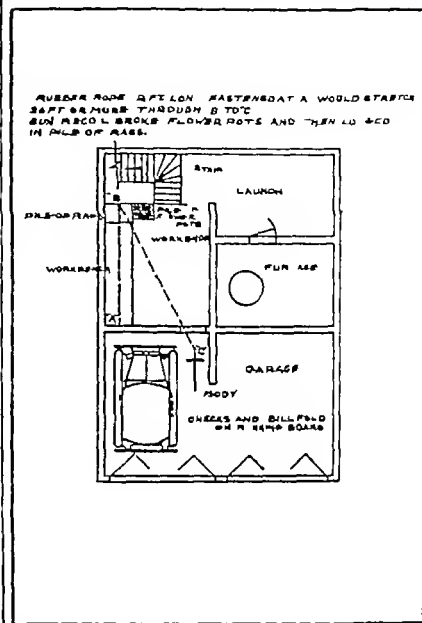

mately three hours, and finally a 32 calibre revolver was found and later identified as the property of the deceased. This came to light in a workshop about ten by twelve feet in area adjoining the garage. It was tied securely to a piece of rubber cord with heavy hempen cord which showed signs of having been broken and retied. The rubber cord was one half inch in diameter and sixteen and a half feet long, placed over the revolver there was a cardboard cone its base at the muzzle and its apex at the handle. Theoretically it seemed that the base of the cone was to be placed in close apposition to the body to deaden the report of the discharge, and also to prevent powder burns on the hands. The rubber cord ran around the leg of Mr X's work bench, through a cotton pillow and burlap bag, and along the undersurface of the bench through a series of holes made through supports under the top of the bench for a distance of about 12 feet. It could not be seen unless the observer was directly under the workbench. It developed that this cord could be stretched into the garage to a point where the body was found a distance of some thirty six feet. The existence of this ingenious contrivance was revealed by a humble flowerpot that lay freshly broken near the corner of the bench. In the investigation which followed it appeared that Mr X, on the morning of his death, had already transacted some business with a client at the latter's home and had returned to his own home a few hours before the discovery of his body. Mr X was rational showed no evidence of mental upset at the time of this transaction and, on the contrary, appeared to be jovial and in good spirits on leaving his client who apparently was the last person to see him alive.

As the inquiry went on, startling facts began to appear. Mr X was heavily insured and policies provided for double indemnity in case of accidental death. He was financially involved and was being pressed by creditors for payment of his several outstanding obligations. His home was heavily mortgaged.

On completion of the investigation it was officially decided that Mr X came to his death by suicide. Evidently the deceased assumed that on the discharge of the revolver with the attendant entry of the bullet into his body his muscles would relax and that the revolver attached to the elastic cord, would fly back into the workroom and conceal itself in the cotton pillow and burlap under the bench, thereby hindering or possibly preventing discovery. However, in passing through its return course the weapon struck the flowerpot which deflected it and this prevented its entire concealment. (See diagram.)

The ingenuity and knowledge of the suicide often went to dispel the appearances of self imposed death. It is frequently his aim to create an out-of-ordinary atmosphere, purposely to

mislead. The result is that commonly, the devices employed are unique in design and the method of procedure seems apparently novel. Yet it can be said only rarely that both the device and plan are original. The case under consideration illustrates this. Although it seems quite unique in design and completion this case is paralleled by the suicide of a Midwestern farmer who shot himself outside his barn and

whose pistol was found under the barn attached to a piece of rubber which had drawn it to its hiding place. Gross' records what is believed to be the first case of this sort and which occurred in Vienna toward the end of the last century. And in fiction the lovable Sherlock Holmes finds the solution of a gripping mystery in the discovery of the lethal weapon in the river into which it had been hurled by a contrivance similar to the one here employed.

None will deny that the ultimate determination of the reason for these gruesome tragedies often depends on the true discernment of the value of seeming insignificant facts. No fact is too subtle or too minor to be unworthy of notice. There is no such thing in these cases, as too many facts. Investigations must be pains taking persistent and if you will, even painful thorough.

THE GOLDEN AGE OF MEDICAL ENDOWMENTS

BY HENRY A CHRISTIAN, M D *

DURING the three decades, 1900 to 1930, medical education in the United States of America was supported increasingly bountifully by gifts for endowment and immediate use, rich men gave extremely generously for improvement of medical education, for increased facilities, for investigation of medical problems and for larger and better hospitals in which to care for the sick

All parts of our country received such gifts, some parts more bountifully than others, but in no section were such gifts small in amount. Practically all medical schools had their financial resources greatly augmented. The actual plan of management and teaching in vogue in the medical schools seems to have influenced gifts but little, actually very various types of organization are found in these medical schools that were helped so generously, gifts to improve medical science and medical practice by enlarging the financial resources of medical schools and hospitals came, apparently in spite of, rather than because of, form of organization, it made but little difference whether hospitals were related to medical schools or not, everywhere money came. The period 1900 to 1930 was one of unprecedented giving to all aspects of medicine.

A study of the budgets of a group of fifteen representative medical schools shows the in-

crease in financial resources, and so how little influenced by form of organization and by geo-

*Christian Henry A.—Hersey Professor Theory and Practice of Physic Harvard Medical School For record and address of author see This Week's Issue page 700

CHART 1 shows ratio of the budgets of fifteen medical schools (1900-1930) illustrative of the data of table 1

graphic distribution. What has happened to the annual budgets by decades from 1900 to 1930 in these representative medical schools is graphically presented in chart 1, which be it noted, is on a ratio basis wherein equal vertical increments correspond to equal proportional increases in expenditure. For five schools no budget is shown until 1910. Medical school No. 14 has had proportionately the greatest augmentation of budget (thirty-one fold), No. 1 comes next in increase (twenty-two fold), No. 13 and No. 5 rank next with increases of sixteen and fifteen fold respectively. No. 10 began in 1900 with the largest budget, increased six fold and was outstripped in total budget in 1930 only by medical schools No. 4 and No. 5. Medical schools Nos. 4, 5 and 10 in 1930 had budget expenditures of over \$1,000,000.00 while medical schools Nos. 1, 11, 12 and 14 spent between \$715,000.00 and \$830,000.00 each. Table 1 shows the actual budgetary expenditures of each school for 1900, 1910, 1920 and 1930 and the proportional increase from 1900 to 1930. The geographic dis-

tribution of these schools was as follows: two in the New England States, three in the North Atlantic States, one in the Mid Atlantic States, two in the Southern States, five in the Mid Western States and two in the Pacific States.

Tha thirty years from 1900 to 1930 comprised the golden age of medicine so far as financial support was concerned. The past few years have shown a shrinkage of assets and curtailment of expenditure, not infrequently very serious retrenchments have been necessitated. None can foresee the future, but it seems very probable that the day of great gifts for medicine is over; certainly this will be true for many years to come. Will governmental support replace private endowments and gifts? What will be the results of such a change? Here is a serious problem whose satisfactory solution will demand the best thought of medical men. This is a challenge to those now just commencing activity in medical schools and hospitals; they will be the ones to solve this problem.

LIFE EXPECTANCY

According to Dublin and Lotka. In their book on "Length of Life" during the Roman Empire a baby's expectation of life was between twenty and thirty years. One hundred years ago in England it was forty years. In the United States it is now fifty-nine years for boys and sixty-two years for girls.

Dr. Alexis Carrel, Nobel laureate in medicine and otherwise famous, interjects an unpleasant thought for people of the third decade in a report to the *New York Times* expressing the opinion that a middle-aged individual has less chance of reaching eighty than his grandparents had.

He claims that resistance to fatigue, sorrows and worries has decreased and that modern men easily break down. He advocates a new type of scientist whose functions should be to concentrate on the study of human problems.

"HEALTH FOODS AND DRUGS SEIZED BY PURE FOOD OFFICIALS"

Stocks of health foods on sale at Washington D. C., and Boston were examined in February by inspectors of the Federal Food and Drug Administration and six items found in violation of the law. They were labeled as so to give the impression that they were foods possessing special remedial properties. The Administration says they were mixtures of various food and non-food ingredients and had no greater nutritive value than

ordinary foods. Furthermore, in some of them there were medicinal ingredients which in the view of enforcing officials have no rightful place in any thing sold as food.

The available stocks were seized on charges of misbranding. The charges as to each item are explained as follows: "Correcol," a mixture of medicinal seeds similar in characteristics to psyllium with gum karaya (a vegetable gum) was labeled as a "colon food" although neither ingredient had any food value. It was further claimed that the product would set up normal intestinal activity which was beyond its capabilities.

"Hanser Potassium Broth" made of dried seneweed, alfalfa, okra, potato starch, beet and rhubarb leaves contained nothing especially warranting its name, according to the allegation. The ingredients provided no more potassium than can be obtained in the normal wholesome diet. A representation that the article was a health product was similarly held unwarranted.

"Slim" which the manufacturer called "a delicious non-habit forming beverage" was in reality a mixture of senna, orange peel anise, bladder wrack (a seaweed), huckthorn bark, dried apple and cantenary flowers. The Administration fully charged that this product, containing mostly medicines with only one true food ingredient was not a beverage. Also, claims for the reduction of weight were held to overreach the worth of the mixture which could have a laxative effect only.—*Bulletin U. S. Department of Agriculture*

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 22141

PRESENTATION OF CASE

A thirty-five year old white American garage owner was admitted complaining of pain in the chest.

The patient was perfectly well until four years before entry when he began to suffer from a steady aching pain in the arches of both feet. There was no reddening but there was said to be some slight swelling and tenderness. The duration was not recorded. He continued his daily activities and shortly afterward began to notice some dyspnea on exertion. This continued with gradually increasing severity. About a year later while in bed the patient had his first attack of chest pain. The pain was localized to the region of the left nipple and was associated with profuse perspiration. No other details were noted. About this time he began to be "quite nervous" and visited a physician who immediately referred him to a cardiologist. He was given digitalis and nitroglycerin but had no further attacks for several months. At this time precordial distress began to recur with increasing frequency. The pain now radiated down the anterior surface of the left arm to the wrist and was associated with profuse perspiration and palpitation. Relief was obtained fairly promptly by the administration of one to three nitroglycerin tablets. About a year before entry he was compelled to discontinue work because of the pain which now occurred several times daily. The distress was often not associated with either exertion or excitement. It continued to occur daily for the three succeeding months, which he spent in bed, but evidently the attacks were lessened in severity and frequency. For the remainder of the period up to his admission he led a bed-and-chair existence. An occasional short walk was permitted but this invariably precipitated an attack. He took as much as a grain of morphin without relief of pain. Gradually the frequency again increased until he suffered twelve to fifteen episodes daily, often while at complete rest and frequently awakening him from sleep. There was no orthopnea. He developed a slight nonproductive cough about a week before coming to the hospi-

tal. He had no acute joint distress although for two years he had had occasional slight pain with movement of the left shoulder and upon flexing his fingers. During the four years of his illness his weight had decreased from 190 to 145 pounds.

He had a series of twelve operations for fistula in ano done twelve or fourteen years ago.

Physical examination showed a cooperative young man complaining of pain under the left clavicle. There was profuse perspiration. The skin showed ashen pallor. The apex impulse of the heart was felt in the sixth interspace, 13 centimeters from the midsternal line. A systolic thrill was palpated at the aorta and a diastolic at the apex. A blowing systolic and a rumbling diastolic murmur were audible in the mitral area and both systolic and diastolic murmurs were also audible at the aortic area. A pistol shot sound was heard over the femoral vessels and a faint capillary pulsation was observed inside the lips and in the nailbeds. The pulse was full, pounding, and said to be of Corrigan type. The blood pressure was 160/110. There was pain on movement of the proximal phalangeal joints of the right hand and the left shoulder.

The temperature was 98°, the pulse 100. The respirations were 20.

Examination of the urine was negative. The blood showed a red cell count of 5,140,000 with a hemoglobin of 75 per cent. The white cell count was 13,700, 65 per cent polymorpho-nuclears. A Hinton test was negative. A blood culture was negative. An electrocardiogram showed normal rhythm with an occasional ventricular extrasystole. The P-R interval was 0.2 of a second. The Q-R-S was 15 of a second. The Q-R-S complexes were split, and the T waves extended in the opposite direction. There was left axis deviation.

X-ray examination of the heart showed marked enlargement in all directions but more prominently downward and to the left. The aorta was not dilated. The lung fields showed diffuse mottled dullness, more marked on the left side and increased density in the bases.

On the fourth day a paravertebral alcohol injection of the first to fourth left thoracic nerves was done after which the patient rapidly developed left pupillary, sudomotor and vasomotor paralysis in the upper portion of his body. Shortly afterward he complained of acute pain in the left chest. This was associated with some dyspnea and cyanosis, and a friction rub was heard in the left upper thorax. The pain was relieved somewhat by strapping the chest but the distress continued for about two days, after which the patient appeared to improve. An x-ray taken four days postoperatively showed some fluid in both pleural cavities and increased dullness in the lung bases. He had no further anginal attacks but suffered from paroxysmal

attacks of dyspnea. Nine days postoperatively he had pain high in the chest bilaterally which was aching in character and more severe on the left side. The pain persisted throughout the night and a friction rub was heard in the left upper axilla. On the following day the patient, whose condition had remained fair and duly gasped and died.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED Taking this history as it is given, it is a pretty weak description of rheumatic fever. It seems to me this story suggests the gradual onset of angina to the point of angina decubitus. Of course, at his age, without any definite rheumatic history in the past, it is a fairly good picture of cardiovascular syphilis. If, on the other hand, you take what is given you in the physical examination later on at its face value, then your point of view changes. Perhaps the description of the arches of the feet is put in to suggest that he was a rheumatic. However, I do not see how that description can be of value as a definite manifestation of rheumatic fever. You will see that he first began to have anginal pain on exertion which was relieved by nitroglycerin and gradually had to take to his bed. He had frequent attacks in bed without exertion, to a point where a grain of morphia was necessary to relieve pain. There is no episode which is described here, however, which would make us think he had a definite occlusion of any of the coronary arteries.

If this record is correct it is perfectly obvious that with a palpable diastolic thrill at the apex and palpable systolic thrill at the base in the aortic area and corresponding murmurs one must make a diagnosis of rheumatic heart disease with mitral stenosis, aortic regurgitation and aortic stenosis. Therefore the case falls at once into the rheumatic group, also, as you will see later the Hinton test is negative, which helps to rule out the syphilitic suggestion. He was obviously in shock from pain with the ashen pallor and the profuse perspiration that occurs from any pain, gallbladder pain, ureteral colic, a true coronary thrombosis or from severe anginal pain.

Presumably there was no bacterial endocarditis. There was no anemia, and at least one blood culture was negative. The P-R interval was at the upper limit of normal. The Q-R-S complexes were split, with the T waves extending in the opposite direction, indicating intraventricular block, presumably left bundle branch block, which indicates severe myocardial damage, or coronary disease. One cannot tell either by physical examination or electrocardiogram whether this man ever had a definite coronary occlusion but it does indicate that he has severe myocardial damage with angina and so

presumably a good deal of coronary disease. May I ask Dr Holmes to look at the x rays?

X RAY INTERPRETATION

DR. GEORGE W HOLMES The x ray examination covers only a period of three days. This is one of the first films taken and it shows a definitely enlarged heart. The enlargement is almost wholly to the left and appears to be left ventricular enlargement. It is possible of course, that the right ventricle is also enlarged but the horizontal position and general shape is more suggestive of left ventricle. In addition he has definite changes in the lung roots with thickening and mottling extending out into the lung from the roots—the appearance of stasis rather than bronchopneumonia. There is a slight increase in the width of the supracardiac shadow if we look at the films taken in the oblique view. We have a fairly good outline of the aorta and I think we can safely say it is not dilated. If that observation is correct he probably does not have aortic or hypertensive heart disease.

We have a film taken three days later in which there appears to be considerable change in the heart during the interval but part of it may be due to a difference in the way in which the films are taken. This is a portable film and taken at a shorter distance and part of this increase in size is due to that. It does look as if the heart were a little larger and the changes in the lung became more marked.

DIFFERENTIAL DIAGNOSIS CONTINUED

DR. BREED Before we go into the definite cause of his death I should like to say a word about the question of when his rheumatic infection began. I doubt very much that it began four years prior to his entry, when he complained of painful arches. Such rapid progress from a mild rheumatic infection in a man of thirty along cardiac lines is very unusual. I should assume that he had had a rheumatic infection previously and that for a number of years he probably had rheumatic heart disease without symptoms. Whether the pains in his arches were due to rheumatic fever I think is entirely academic and it is of no particular value to decide that question here. He was given the alcohol injection because of angina, and I should therefore doubt that he had had an occlusion prior to this because he probably would not have been selected for such a procedure if it had been known that he had had any amount of cardiac infarction. We know, also, that people with rheumatic heart disease are prone to early coronary disease. I think we can rule out syphilis very well. Now what did he die of? I think that is somewhat academic too because he did not have any particular episode lasting a few days, and the ninth day he died rather

suddenly having had some chest pain twenty-four hours previously. There are three possible causes of his death. One of them is a large occlusion, one a pulmonary embolus and another is a rent in the aorta or in the myocardium. I suppose we are expected to say one, two and three on this. The appearance of the friction rub after the pain not over the precordium but high in the left axilla is not very helpful. Just for the sake of making it interesting I will put (1) pulmonary embolus, (2) large fresh occlusion with infarction (a little rapid for that but it might be big enough) and (3) some mechanical tearing or rupture of the aorta or of the myocardium.

CLINICAL DISCUSSION

DR EDWARD F BLAND This was a very unusual case and we believe it belongs in a relatively rare group which Lewis described in part in 1931.

There are a few interesting points that were not brought out in the story. In the first place he was only thirty-five years of age when he died. He had the beginning of his arthritic symptoms at thirty-one. Prior to that he had had a number of physical examinations for insurance and his heart had been normal. Furthermore, shortly after the onset of his arthritic symptoms his heart was said to be involved and within one year of the onset of rheumatism he began to have angina pectoris, within two years he was bedridden with angina pectoris decubitus. He was referred from Ohio to Dr J C White in this hospital for surgical relief of the pain. Formerly he had been accustomed to take as many as fifty nitroglycerin tablets during twenty-four hours. When he entered here we felt he had some form of active cardiovascular disease. We believed lues had been ruled out and thought it probably rheumatic in nature because of the repeated joint pains. This impression was further supported by the following findings: slight periaortic swelling around the small joints of the hands, an elevated sedimentation rate and a persistent leukocytosis, together with a P-R interval by electrocardiogram of 2 of a second. Clinically we were certain he had active rheumatic disease. This was further suggested by the atypical form of angina pectoris which he had. Lewis has fully described the syndrome. The attacks usually come at night without adequate provocation and are associated with a striking rise in blood pressure. We have observed one similar case at the House of the Good Samaritan where the blood pressure rose from 160 systolic to over 300 systolic during these attacks. They are accompanied by a sinus tachycardia of 130 to 140 with profuse sweating and flushing of the skin and considerable associated respiratory difficulty, all of which were present in this patient. Furthermore, in the milder attacks they may

not have pain, but only the associated circulatory phenomena. It is only with the severe attacks that they have typical anginal pain. After the alcohol injection his angina pectoris was completely relieved but he continued to have paroxysmal attacks of the profound circulatory disturbances which had been previously noted. As to the exact cause for his sudden death, we had no adequate explanation except, as Lewis pointed out, they are prone to die suddenly.

DR EARLE M CHAPMAN What percentage of cases of proved cardiovascular lues may have a negative Hinton?

DR BLAND There are figures from Baltimore indicating about 15 per cent.

DR MALLORY That is the Wassermann.

DR BLAND Yes.

DR TRACY B MALLORY The Hinton is certainly more sensitive, so I should think you could cut that figure in half.

DR BREED Does anyone here think this man had cardiovascular syphilis?

DR BLAND One further point I would like to make. All of these people with this form of angina pectoris have been relatively young, all have had free aortic regurgitation and in our experience it has been rheumatic in origin.

CLINICAL DIAGNOSIS

Rheumatic heart disease, aortic and mitral valve involvement

DR WILLIAM B BREED'S DIAGNOSES

Rheumatic heart disease
Mitral stenosis and regurgitation
Aortic stenosis and regurgitation
Pulmonary embolus

ANATOMIC DIAGNOSES

Subacute aortitis and aortic endocarditis—unknown etiology
Aneurysm of the mouth of the left coronary artery
Aortic insufficiency
Hypertrophy and dilatation of the heart
Chronic passive congestion
Anasarca
Congenital malformation of the right kidney

PATHOLOGIC DISCUSSION

DR MALLORY Let me show you first the picture of this man's aorta and aortic valve. One of the commissures of the aortic valve was cut directly through in opening the heart but the other two show clearly. Their points of attachment to the aorta appear to be much lower than normal so that the sinuses of Valsalva and the mouths of the coronaries are more evident than usual. There is no interadherence but neither is there definite separation. The cusps are markedly thickened and appear to be

stretched rather taut across the dilated ring. There are no vegetations on them. The walls of the sinuses and the first 25 centimeters of the ascending aorta show a pannus-like overgrowth of pink, wrinkled fibrous tissue. Only

the minutest atheromatous flecks could be made out on close scrutiny. The upper margin of involvement is irregular but very sharp and the aorta beyond is perfectly normal.

The mitral, pulmonary and tricuspid valves were all negative—not the slightest suggestion of rheumatic involvement and their circumferences were all within normal limits. The circumference of the aortic valve was 10 centimeters, 2 centimeters above normal limits so there could have been no stenosis of either the aortic or the mitral. Both right and left ventricles were dilated and their walls were markedly hypertrophied. The heart weighed 900 grams.

The margins of the sinuses of Valsalva are difficult to make out because of the endarteritic process but it is evident that the mouths of both coronary arteries are above them and arise from the aorta proper. The mouth of the left one was involved in a small aneurysmal dilatation 1 centimeter in diameter and 0.5 centimeter in depth, which is not apparent in the photograph. The mouth of the right one was narrowed and can be seen as the crescentic slit just medial to the left hand commissure. Beyond their mouths both main coronaries and all their major branches were entirely negative.

Histologically the intima of the involved areas shows a marked overgrowth of fibrous tissue with little or no inflammatory infiltration. The media under these areas is invariably highly vasen-

larized with foci of absorption of muscle cells and elastic lamellae. The penetrating vessels are often surrounded by cuffs of lymphocytes. In the adventitia the perivascular inflammatory infiltration is very marked. In other words, the picture is a textbook one for fairly acute syphilis of the aorta. Whether such a diagnosis is justified however, is open in my opinion to real doubt. Perhaps we had best postpone the final discussion till after the next case. Microscopically numerous small foci of muscle cell absorption without leukocyte reaction were found scattered irregularly throughout the myocardium. No Aschoff nodules were demonstrated.

Outside the heart and aorta we found little of importance. There was a rather marked hypertrophic arthritis of the spine. There was, of course, moderate anasarca and marked chronic passive congestion. The right kidney was anomalous, showing no development of the upper pole.

DR. BREED. I would like to make one comment about the mitral valve. We are beginning to be willing to accept a mitral diastolic murmur before death without presupposing stenosis but we are not as a rule willing to accept a definite diastolic thrill in the mitral area without diagnosing stenosis. Therefore, I should like to cast some doubt on that observation. It is not easy to time thrills. Dr. Bland saw this patient, and so I should like to ask him if he is perfectly clear in his own mind that there was a definite diastolic thrill in the mitral area.

DR. BLAND. No, I agree with Dr. Breed. Perhaps it would help if I read this short description of my findings. 'Cardiac sounds at the base are masked by a loud harsh systolic and blowing diastolic murmur. At the apex is a slight systolic and a moderate mitral rumble (no thrill).'

CASE 22142

PRESENTATION OF CASE

First Admission. A twenty five year old white American laborer was admitted complaining of pain and swelling of the joints.

About six years before entry the patient began to have pains and some swelling in his feet. These persisted for about two years, at which time strapping and orthopedic treatment relieved the distress. However for the two years preceding admission both feet and ankles became intermittently swollen and painful. One and a half years prior to entry his right wrist became swollen and motion was painful. About a year later his right heel became swollen and was quite tender. X-ray examinations showed spurting in this region. For four months before entry he had frequent pain and some stiffness in his lower back. Despite these symptoms he

continued with his work. There were occasional night sweats and slight morning cough of some two years' duration.

He had had an acute attack of gonorrheal urethritis two and a half years before entry and again a year later. Both attacks subsided promptly with vigorous medical care.

Physical examination showed a well-developed and nourished young man in no discomfort. Several small discrete nodes were palpable in the cervical, axillary, epitrochlear, and inguinal regions. The lungs were clear. The heart was not enlarged. The sounds were normal. The blood pressure was 110/65. Tenderness was elicited over the tenth, eleventh and twelfth dorsal spines. There were swelling and limitation of motion of the right wrist joint. Tenderness was elicited over the metatarsal arches and about the insertion of the right Achilles tendon.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red cell count of 5,500,000, with a hemoglobin of 100 per cent. The white cell count was 9,600, 55 per cent polymorphonuclears. The sedimentation rate was 85 millimeters per minute. A gonococcus complement fixation test was negative. The uric acid was 2.6 milligrams per cent. A Hinton test was negative. The basal metabolic rate was minus five. Prostatic fluid was negative for gonococcus. Gastric analysis showed free acid. A sugar tolerance test showed a normal curve.

X-ray examination showed no evidence of dental or sinus infection. There were proliferative changes about the margins of the right wrist joint. The vertebral column was negative. A gallbladder series and barium enema were negative. The lungs were clear and the heart was normal.

The patient's condition remained essentially unchanged. His course was afebrile save following the administration of typhoid vaccine intravenously and gonococcus vaccine subcutaneously, at which times he had sharp rises in temperature. He was discharged on the twenty-sixth hospital day.

Second Admission, three months later

The patient remained fairly comfortable for two months after discharge. Thereafter there was recurrence of all joint pains in both wrists, lower back, and left sacio-iliac regions. The right heel remained persistently painful and he returned to the hospital for relief of this symptom.

Physical examination showed the patient's condition to be essentially unchanged. There was tenderness over the ninth dorsal spine with limitation of spinal movement. There was tenderness over the right wrist joint, proximal joints of the first and second left metatarsals and posterolateral aspect of the right heel.

The blood showed a white cell count of 10,800, 40 per cent polymorphonuclears and 60 per cent lymphocytes.

A bursa was removed from beneath the right Achilles tendon and the patient was discharged five days later.

Final Admission, nine months later

Except for intermittent recurrence of pain in the various joints the patient felt fairly well and six months before returning to the hospital he worked in a hayfield for about a month. At the end of that time increasing joint pain precluded such activity. He stated that he felt a little weak thereafter but was not obviously ill until two weeks prior to reentry. He then developed slight productive cough, palpitation and dyspnea with moderate exertion. These symptoms progressed rapidly in severity.

Physical examination showed the patient to be well nourished, orthopneic, and moderately cyanosed. His eyes were staring and there was slight fullness of the neck veins. The tongue was furred and the throat was angry red. The heart was found to extend 4 centimeters to the right of the midsternal line and 10 centimeters to the left in the sixth inter space. Rough aortic systolic and diastolic murmurs were heard best in the carotids. A_2 was absent. A systolic bruit was audible in the pulmonic area, and P_2 was accentuated. A presystolic thrill and murmur were present in the mitral area. The blood pressure was 125/65. Fine moist rales were audible at both lung bases. The liver was tender and extended three fingerbreadths below the costal margin. The right wrist joint was partially ankylosed and there was swelling of the left ankle. No note of edema was made.

The temperature was 100° , the pulse 100. The respirations were 30.

Examination of the urine showed a trace of albumin but was otherwise negative. The blood showed a red cell count of 3,800,000, with a hemoglobin of 60 per cent. The white cell count was 10,500, 78 per cent polymorphonuclears. The stools were negative. The nonprotein nitrogen of the blood was 40 milligrams. Repeated blood cultures were negative. The sedimentation rate was 38 millimeters at the end of one hour. The vital capacity was 1,500 cubic centimeters. An electrocardiogram showed normal rhythm with evidence of left bundle branch block. Another gonococcus complement fixation test was negative.

X-ray examination showed a mitral shaped heart with marked pulmonary artery enlargement.

Shortly after admission a pericardial friction rub appeared. The temperature continued to be elevated and fluctuated between 99° and 102° . At the end of the second week the cardiac dullness appeared to be increased and the patient became quite markedly dyspneic. A pericardial tap afforded no relief and on

the following day while receiving intravenous glucose, he suddenly became markedly cyanotic, went into collapse, and died shortly afterward on the fifteenth hospital day, thirteen months after the first admission.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD B. SPRAGUE If we leave out all the inside of this record and think of the first part and the last part, we have a boy who at the age of nineteen begins to have joint pains which are troublesome off and on for the rest of his life and he dies seven years later with evidence of valvular disease. This would seem to be all right for setting up a diagnosis of rheumatic heart disease. It is only when you look at the rest of the data in the record that you think this might be a diagnosis to shoot at rather than to accept offhand. I should like to know what sort of arthritis he had during these years. Apparently it troubled the people in the hospital as much as it troubles me. He certainly was thoroughly investigated so far as the etiology of his arthritis is concerned. It was apparently a proliferative affair with partial ankylosis and calcification of a joint. I do not know whether there is an intermediate type of infectious arthritis which is the same thing as rheumatic fever, but I do feel that we see patients who have some joint changes of a permanent nature associated with rheumatic fever and who have cardiac changes typical of rheumatic heart disease. We have come to look at such a patient on the ward from the standpoint of diagnosis in this way—we listen to the heart in order to make a diagnosis of the kind of arthritis he has. If the patient has rheumatic heart disease what he has in his joints is rheumatic fever. I am not at all impressed in the present case with the fact that the gonorrheal infection bears any clear relationship to this unless it was a further activating agent. I should like to hear from Dr. Baner some time as to what kind of arthritis the patient had.

At his first admission he had an entirely normal heart. You can see that his various tests were entirely normal except the sedimentation rate. I take it that this was elevated and on the second admission it was also elevated but reported a different way. He had no increase in uric acid in the blood. The Hinton test was negative. You will see that at times he was an orthopedic problem and had treatment for pains in his feet and later on he became a surgical orthopedic problem with dissection of a bursa and other times was a straight medical problem. However, he was able to leave the hospital after this palliative operation but returned in nine months with all these findings in his heart. That is the disturbing thing that in such a short time he could develop all this cardiac pathology. He has a rough aortic systolic and diastolic murmur which was heard

best in the carotids but I take it they were also heard over the heart, and the aortic second sound was absent. That certainly suggests something wrong with the aortic valve and it is very difficult for me to believe that he could develop rheumatic aortic stenosis, which this suggests, in nine months. He had a presystolic thrill and murmur at the mitral area. Again I feel that he could not have developed mitral stenosis.

DR. WALTER BAUER I did not think that there was a presystolic thrill. The only murmur I remember hearing was the aortic diastolic one.

DR. SPRAGUE He came in this last time with more evidence of active infection. He had some anemia and his temperature rose to 102°. The question of bacterial endocarditis apparently was quite seriously considered because he had many blood cultures, consistently negative. An electrocardiogram showed left bundle branch block. Could we have some report about the x-ray? Dr. Holmes?

DR. GEORGE W. HOLMES These are films of the chest. This is the early film and I think it shows normal heart and lungs. It is possible that there is a little widening across the aortic arch. It was taken at full inspiration and I think we would have to interpret it as normal. A later film, this again is not a seven foot film, probably a portable film very much underexposed and distorted. We cannot see a considerable part of the heart outline or of the lung structure. I think this probably represents the upper border of the heart. Here is the left border a somewhat triangular shaped heart of the type we see in mitral disease or dilatation and in addition we have the changes in the lung which go with passive congestion. I do not believe that these findings help much in the diagnosis. He has no dilatation of the aorta. That might help you some.

Was a pericardial friction rub heard? That is of importance.

There is a rough spur on the undersurface of the os calcis. I do not know that it is of any significance.

DR. SPRAGUE Do you think it is significant of gonorrheal infection?

DR. HOLMES They are said to be more common with gonorrheal infection but they also may be due to trauma.

DR. SPRAGUE The statement about the pericardial tap is rather ambiguous to me.

DR. EDWARD A. GALL There was about 100 cubic centimeters, clear at first and bloody toward the end.

DR. SPRAGUE The possibilities here seem to be rheumatic carditis or an acute bacterial process. We might mention the possibility of lues in this case although the Hinton is negative and the patient is three years younger than the youngest patient with fulminating luetic

aortitis that we have had here, I believe I do not believe that he has bacterial endocarditis due to the gonococcus. It seems to me that his gonorrheal infection quieted down and there was too much time in between for this to be an acute process from that and statistically the figures are very much against it. I believe we have not had any case autopsied here of acute gonorrheal endocarditis. Against bacterial endocarditis is the fact that we have no evidence of petechiae, negative blood cultures and essentially negative urine, and the occurrence of pericarditis. Pericarditis does occur with acute or subacute bacterial endocarditis but it is relatively rare. The signs in the heart if we are to explain them on the basis of acute bacterial endocarditis make one think that large vegetations might be present in the mitral and aortic valves which would produce, both of them, enough obstruction to suggest a stenosis of the valve. That can occur. Also, there may have been enough ulceration of the aortic cusp to result in the disappearance of the aortic second sound. The left bundle branch block could be caused by a metastatic abscess in the region of the left branch of the bundle of His or obstruction in the region of the coronary ostia, or could, of course, be due to active rheumatic carditis. On the whole I should think that the rapid progress in this case, so far as the heart is concerned, pointed to a relatively acute bacterial endocarditis without clear evidence that the several years of joint pain had resulted in any definite rheumatic process on which it was engrafted.

CLINICAL DISCUSSION

DR BAUER: This individual did not seem to be much of a diagnostic problem so far as his joint disease was concerned until the time of his last admission. As you can see from the detailed arthritic work-up, he was thought to have arthritis. We hope some day soon we shall have sufficient data of this sort to enable us to discontinue this detailed statistical type of study.

We thought we were dealing with an individual who had proliferative arthritis or the chronic rheumatoid type of arthritis. The question of gonorrheal arthritis was raised from time to time primarily because of the fact that he had had an asymmetrical type of arthritis rather than a symmetrical type, secondly, because he did have spurs, and thirdly, because he had Achilles tendon involvement. We do know that we can see atypical rheumatoid arthritis which is anything but symmetrical, although a larger percentage of patients with the disease have symmetrical joints involved. We further know we can have spurs from other causes than gonorrhea, such as trauma. We also know we encounter calcaneal spurs in the chronic rheumatoid type of arthritis. Given an individual with arthritis and Achilles tendon involvement one

should always appreciate that the two most likely things to cause such involvement are either a gonorrheal infection or gout. However, we do occasionally see Achilles tendon involvement in rheumatoid arthritis.

He was followed in the arthritic follow up clinic as an uncomplicated case of rheumatoid arthritis. When one encounters a patient with chronic progressive arthritis of years' duration he can feel perfectly safe in betting a thousand to one that it is not due to the gonococcus. In other words, the gonococcus is not responsible for a chronic progressive type of arthritis of years' duration. It does cause arthritis which may disable a patient for weeks or months. The patient may recover without residual joint changes. In other instances the patient may recover with considerable evidence of joint change or damage in one or more joints. Once such changes have occurred subsequent use of the joints may produce a progressive traumatic arthritis. In such cases we are dealing with a traumatic or degenerative type of arthritis secondary to faulty joint mechanics resulting from the previous gonorrheal arthritis. Certain individuals have recurrent attacks of gonorrheal arthritis but in such instances the patient is symptom-free between attacks. Such patients do not suffer from a slow, chronic, progressive, deforming arthritis extending over a period of years such as we see in rheumatoid arthritis.

DR SPRAGUE stated that given a patient with arthritis and rheumatic heart disease, the presence of rheumatic heart disease means that the joints are part and parcel of a rheumatic fever infection. I cannot agree with this statement. In certain instances this is undoubtedly correct, in others it is not. I do not remember what I wrote in the record at the time of this man's last admission. As I remember the case, my best guess would have been "God knows." I believe I thought that we were dealing with an individual with—I will read the notes.

"We have never been too certain of the type of arthritis present in this individual although we had previously favored a diagnosis of a specific infectious arthritis rather than rheumatoid arthritis. Although he has had arthritis two or three times we have no absolute proof that those episodes were due to gonococcus. The complement fixation tests have always been negative."

There is something missing in the history, that is, he had had two attacks of arthritis, the first attack having appeared six weeks prior to his first hospital entry.

"The question is whether we are dealing with rheumatic fever and rheumatic pericarditis in an individual who has had rheumatoid arthritis for seven years. This is very important from the etiologic point of view. Are rheumatic

fever and rheumatoid arthritis due to the same etiologic agent? At present we have no way of proving it."

The local doctor when written to could not tell us that he had found Gram negative diplococci in the prostatic smears obtained at the time of the first attack of arthritis.

At the time of his last admission I thought he had one of two things either an acute endocarditis or an active rheumatoid pericarditis in addition to the previously existing rheumatoid arthritis.

DR. FREDERICK T. LORD: I saw this patient only at the time of his first admission. The two attacks of gonorrhea occurred some time after the onset of the arthritis and there seemed no reason to assume that he had had an earlier attack. Absence of a history of gonorrhea preceding the arthritis and our failure to prove the presence of gonorrheal infection led us away from the diagnosis of gonorrheal arthritis and we made a diagnosis of infectious arthritis.

CLINICAL DIAGNOSES

Rheumatic heart disease
Aortic stenosis with regurgitation
Mitral stenosis
Pericarditis with effusion
Congestive failure
Pulmonary embolus

DR. HOWARD B. SPRAGUE'S DIAGNOSES

Subacute bacterial endocarditis involving the aortic and probably the mitral valves
Chronic infectious arthritis

ANATOMICAL DIAGNOSES

Subacute aortitis and aortic endocarditis of unknown etiology
Hypertrophy and dilatation of the heart
Thrombosis of the right auricular appendage
Pulmonary embolism
Chronic passive congestion
Hydrothorax, bilateral
Chronic infectious arthritis

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY: This man's heart except for its slightly smaller size looked almost identical with the preceding one. It weighed 580 grams. There was the same type of involvement of the aortic valve and then the same queer fibrous growth over the intima of the first portion of the ascending aorta. In this case, however, the lesion extended only a centimeter up the aorta but balanced this by extending about the same distance down over the ventricular endocardium below the aortic valve. Microscopically the picture is very similar to that in the preceding case though it appears slightly more acute. There is again a marked fibrous thickening of the intima with

swollen active looking fibroblasts but little leukocytic infiltration. The media shows focal absorption of muscle cells and elastic fibers and marked vascularization. There is more leukocytic infiltration in these slides with some polymorphonuclears, many monocytes and many lymphocytes. The vessels of the adventitia show perivascular cuffing with lymphocytes and also show definite endarteritis. The findings are consistent with the acute stage of syphilis. With this in mind Levaditi stains were done but no spirochetes could be demonstrated. The myocardium as in the preceding case showed focal areas of degeneration without leukocytic reaction but nothing suggesting either gummatous or Aschoff bodies. The final episode in this case was pulmonary embolism—a single large embolus which apparently arose from a thrombus in the right auricle. Several joints were turned over to Drs. Bennett and Bauer for examination and Dr. Bauer will report on them.

DR. BAUER: I should like to say that the few joints we were able to examine showed changes which we ordinarily call the characteristic changes of an early rheumatoid arthritis. I believe that in this particular case one is almost forced to make two diagnoses unless they are willing to agree at this time that these two diseases are due to the same etiologic agent as some of our New York colleagues would lead us to believe. How would you interpret this case of Dr. Sprague's?

DR. MALLORY: It is evident that the two cases we have discussed this morning are so closely similar that it is only reasonable to assume that they represent the same disease entity. What that is, however, is still a matter of doubt. In each case the anatomic lesion is typical of the acute stage of infective involvement of the heart and aorta a lesion that for two generations has been considered pathognomonic. Yet a considerable array of significant arguments can be marshaled against such a diagnosis. In the first place there are the negative Hinton tests. These are of course not conclusive but seven years' experience with the Hinton test in this hospital has convinced me of its high degree of sensitivity. The frequency with which it picks up congenital cases vascular and bone cases, and neurosyphilis in which the Wassermann is negative makes it seem unlikely that two cases in the acute stage would have been missed. Barring these two cases the Hinton has failed to pick up only one infective aortitis in the last twenty years have demonstrated at postmortem whereas the Wassermann has missed three. The negative Levaditi in case 22141 is again of some significance though the unreliability of all spirochete stains is notorious. The absence of any history of syphilis is worth consideration. As Dr. Sprague pointed out twenty-six is younger than any proved case of aortic syphilis in our experience. The clinical evidence it seems to me is strongly against the diagnosis of syphilis.

What about the validity of our anatomic and histologic criteria? The last ten years have been prolific of discoveries of new diseases of the blood vessels and many lesions that would formerly have been ascribed to syphilis are now recognized as pathologic entities. Rheumatic fever is now known to cause extensive and severe aortitis, which though usually limited to the outer half of the media may cause significant endarteritis as in cases reported by Pappenheimer and Van Glahn and by Perla. Such extensive destruction of the media as these two cases we are discussing today showed has not, however, been reported, and Dr Pappenheimer, who was kind enough to look at these sections for me, was not inclined to believe they were rheumatic.

That other types of aortitis exist, however, is certain. Klinge has described extensive aortitis in malignant hypertension when syphilis

could apparently be excluded. I have personally seen an acute diffuse aortitis as the only anatomic cause of death. It is not impossible that some of these as yet unclassified processes may produce lesions indistinguishable from those of syphilis.

I imagine the majority of pathologists would classify these two cases as luetic. I can certainly offer no positive evidence to the contrary, yet I find myself distinctly skeptical of that diagnosis. We have insufficient positive evidence to claim they are rheumatic but I do not believe that possibility can be excluded, and particularly in Dr Sprague's case the evidence is very suggestive. There remains the possibility of aortic endocarditis of unknown etiology, perhaps the precursor of certain of the mysterious calcific aortic stenoses ordinarily met only in their healed stages in elderly people. I must leave you to make your own choice.

DIABETES AND TUBERCULOSIS

THE Statistical Bulletin of the Metropolitan Life Insurance Company for February comments upon the comparative mortality from Diabetes and Tuberculosis. It has been well known that the mortality rates for the former disease are rising while those for the latter are falling, but many will be surprised to learn that these converging trends are expected to cross each other in the not distant future. For white females the diabetic death rate actually exceeded that for tuberculosis in fourteen states during the two year period of 1933-1934. The male diabetic death rate will equal or exceed the tuberculosis rate at a more distant future because it is generally so much lower than that of the female diabetics. Among the colored population, and in some of the Southern and certain "resort" States, the approach to the tuberculosis rate, on account of its relative height, is much less apparent. The general trend throughout the country, however, is unmistakable.

It is sometimes said that one half of the world

does not know how the other half lives—but it is easy to know in a general way, how the other half dies. What may be more difficult is to ascertain why the other half dies as it does. The declining tuberculosis death rates have been quoted to illustrate the beneficence of everything from mountain air to salt water and in between they have sold a lot of cough drops. The increase in diabetic deaths, on the other hand is not so naïvely explained, indeed the Census Bureau presents us with the paradox that the more successfully we treat the disease the greater will the death rate be. To die of diabetes one used to have to die in coma. Today coma deaths are rare diabetics are kept alive indefinitely. They can live to die of a hundred other legitimate causes and still be classified as diabetic deaths by the Census Bureau. Because the diabetic trait is a maturing one the fact that human longevity is increasing adds many new cases of diabetes to the population each year. These new cases will all eventually be recorded as diabetic deaths—and the longer we keep them alive the greater will be the "mortality" for which we have to answer.

As an elderly physician of the latter part of the last century used to say "Although one should never give up a patient until three days after he is dead no doctor can be expected to save a man from his last illness."

A LEGISLATIVE MISTAKE

AN amendment to Section One Hundred, Chapter One Hundred and Twenty Three of the General Laws of the Tercentenary Edition (House 40) was introduced to the Massachusetts Legislature by Dr Winfred Overholser the Commissioner of Mental Diseases.

This amendment provided in substance that when a person under complaint or indictment for a crime was found by the court to be insane or in such mental condition that his commitment to an institution for the insane is necessary for his proper care or observation pending the determination of his mental condition the court may commit him to a 'State Hospital or to the Bridgewater State Hospital'. The court may then employ experts to examine the defendant and pay all expenses incident to the study. The amendment further provided that examiners thus employed should be physicians registered in this Commonwealth and qualified by training and experience to carry out this procedure.

It is the duty of the Department of Mental Diseases to advise the Commonwealth from time to time of such matters as may be pertinent in dealing with insanity and the Commissioner properly met his obligation, evidently with the purpose of saving the State from error and applying justice to a defendant.

How did the Legislature behave when this

amendment was before it? The House approved and the bill went up to the Senate. There then ensued a disgraceful exhibition of opposition to a plan which would, if adopted, make court procedure more dignified and give assurance of intelligent treatment of a responsibility which will have to be met quite frequently.

During the Senate debate on this bill certain Senators, true to form on other occasions, ridiculed and insulted physicians recognized by the profession as eminent exponents of the application of scientific medicine to human needs. The bill was rejected.

Progress in several attempts to provide this Commonwealth with the best possible medical service has been prevented for many years by such people.

This deplorable state of affairs does not seem to be regarded seriously by the citizens of Massachusetts and is likely to be repeated unless public opinion becomes articulate and sentiment provokes action in improving the quality of statesmanship.

Unfortunately doctors find legislative responsibilities unattractive and few are willing to make the sacrifice involved in entering political life. These recent exhibitions of bad behavior will tend to deter medical men from seeking election to this chamber, but we need them there. The opportunity for honorable service should appeal to those who can afford to give time to it. If this sentiment could be expressed by organized medicine, it might lead some of our doctors to engage in this field of public service. A deliberative body that permits crude and indecent brawling in its proceedings needs the infusion of a dignified membership. The Senate as now constituted seems impotent to correct its faults. How long must we endure these insults?

The Massachusetts Medical Society

THE SCIENTIFIC EXHIBIT

In recent years, medical meetings have made a feature of the Scientific Exhibits. Of ever-increasing merit year by year, these exhibits have become an important feature of the meetings.

According to precedent, the forthcoming meeting of the Massachusetts Medical Society in Springfield promises to include features of interest to its members in the Scientific Exhibit. Modern methods of diagnosis and treatment in both surgical and medical fields are to be emphasized. Two exhibits on cancer treatment promise to be of interest: two on pathology, one on recent advances in chest surgery, another on plastic surgery, one on pneumonia and still another on anemia will engage the interest of all

Recent advances in diagnosis and therapy will be emphasized throughout.

The Scientific Exhibit will, as last year, be in the main hall together with the Commercial Exhibit. All members attending the meeting will find many items of interest in both exhibits.

CORPUS LUTEUM TREATMENT OF THREATENED ABORTION

The diagnosis of threatened abortion is properly made when uterine bleeding or painful rhythmic uterine contractions occur before the twenty eighth week of gestation It is true that many pregnancies otherwise normal which progress to term without treatment are associated with a slight bloody discharge for one or two days usually during the first few months and some such have a few hours of painful uterine contractions However mild such a threat may be the diagnosis remains the same for the sign and symptoms mentioned are due to forces which if unchecked by nature or treatment will finally terminate the pregnancy We attribute contractions either to an increase in the contractile stimulus, emanating probably from the pituitary or to an increase in sensitivity of the fundus by reason of at least a relative diminution of the corpus luteum hormone which normally renders the myometrium insensitive to such stimulus. The cause of the increased pituitary stimulus or of the decrease in corpus luteum inhibition is not known The bleeding comes either from a dissolution of part of the

decidua from an unknown cause which is intrinsically capable of destroying all the decidua or it comes from a separation of a part of the chorion by an unknown cause which likewise is intrinsically capable of breaking the villous contact over the whole decidua basalis In these cases in which abortion is but mildly threatened and recovery spontaneous the factors involved in either the destruction of the decidua or in the separation of the trophoblast on one hand or in the change in pituitary or corpus luteum action on the other hand are promptly neutralized, are compensated for or subside by reason of opposing qualities of either matrix or ovum or both The clinician who would successfully combat the more vigorous threat of abortion must consider the factors for bleeding or for uterine sensitivity, which I have characterized as unknown and consider too what I have called the opposing qualities which are equally mysterious.

Studies of the endometrium of both lower mammals and primates seem to show that the development of the mucosa into the decidua and its maintenance during at least the early part of pregnancy are due to the effect on the endometrium of properly related amounts of estrin and progesterin from the corpus luteum This gland is a biological puzzle Only a fertilized ovum can normally sustain it beyond a limited period,—about fourteen days in human beings, and the corpus luteum in turn is essential to the early development of the ovum If in primates, the corpus luteum is removed in the first third of pregnancy the decidua disintegrates and bleeding occurs, followed by miscarriage. Except in placenta praevia which we mention below, whenever red flow occurs early in human pregnancy we can with what justification recent biological studies give us postulate a disturbance in corpus luteum physiology and either an absolute deficiency of progesterin or a deficiency relative to the amount of estrin present The same may be said of an increase in myometrial activity

There are two theoretical ways of compensating for this partial failure of the corpus luteum One is to substitute for it by supplying the woman with progesterin obtained from the corpora lutea of other mammals This is already commercially available and a synthetic progesterin may soon be on the market The second theoretical way to compensate for progesterin deficiency is to increase its production presumably by encouraging the anterior pituitary to increase its production of the so-called luteinizing hormone More of this later

If one is to substitute a very important detail in the treatment, the proper dosage must be determined Progesterin is marketed in ampoules containing 1 cc of solution of progesterin with stated potency of 1/25 rabbit unit of 1/5 rab-

A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

bit unit, of 1 rabbit unit, and of 5 rabbit units. There is no clinical evidence known to the writer that doses of less than 3 rabbit units have any effect on the *nonpregnant* woman. He has enough clinical evidence to make him think that anything less than repeated doses of 3 rabbit units will *not* affect the nonpregnant patient, whether she gives evidence in her endometrium that there is no active corpus luteum present, or that there is a normal one present.

In the pregnant woman who is threatening to miscarry, either the ovum is normal and alive and therefore worth saving or it is abnormal and fortunately perhaps already dead. If the ovum is good enough to save, biology teaches us there must be present in the patient a corpus luteum which is secreting at least a moderate amount of progesterin,—in all probability, at least as much as the nonpregnant patient produces during the latter half of the normal menstrual cycle. If repeated doses of less than 3 rabbit units of progesterin are not effective on the bleeding mechanism in the nonpregnant patient, or on the pain from essential dysmenorrhea, it seems a fair conclusion that such an amount can have no appreciable effect in the pregnant patient.

The published reports of cases treated with small amounts are quite unconvincing. The "post hoc ergo propter hoc" conclusions drawn from these cases are not acceptable until we learn that we are wrong in believing that in more than 65 per cent of completed abortions, the conceptus is already dead or abnormal when the first threat of miscarriage is made—a belief which is based on careful examination of miscarriage products by competent embryologists. The other 35 per cent of the completed miscarriages are the only ones which concern us, and which obviously need some other treatment than the methods available up to now. Included among these are undoubtedly some cases of early placenta praevia in which purely mechanical separation of the trophoblast from decidua causes the first bleeding which progresses until enough separation has occurred to render the conceptus a foreign body. This, then, of itself invokes uterine contractions by a mechanism unknown. The treatment for these must be preventive, of which we know nothing, or complete rest, of the necessity for which we usually become aware only too late to accomplish anything. The treatment of the other patients, who merely threaten to abort but do not execute the threat, is obviously adequate. It may be that the patients who thus fail to fulfill their threat to abort, and who have normal concepti, will be more easily deterred by progesterin, but to this end they will, in all probability, need larger doses than heretofore, or than any but the richest can afford at the present prices.

If adequate substitutional treatment for a theoretical progesterin deficiency is thus not al-

ways available, the only other compensatory method is stimulation of the patient's corpus luteum to work more effectively. Our only approach to this end is through the anterior pituitary, and we have only theoretical ways of encouraging the anterior pituitary to supply an adequate luteinizing stimulus. Empirically, rest, with its beneficent effect on the central nervous system, and through this on the sympathetic nervous system, and through both, on the adrenals and the thyroid, and, perhaps directly or through this latter effect on related endocrine structures, on the pituitary gland,—rest, has proved helpful in defending against the threat of abortion. To such rest, experience, and some sound biological conclusions, teach us to add an extra supply of what vitamins we are aware of, of the minerals contained in milk, of iron in the presence of anemia, and of iodine or thyroid extract in the presence of even a slight measurable disturbance of thermodynamics. These with a balance of fats, carbohydrates, and proteins are the best agents we have for pituitary support. As the ovum develops, its dependence on the corpus luteum grows less but its requirements of metabolites derived from food grow greater. The same treatment, persisted in, which applies what little we know of human nutrition, then benefits the conceptus directly. There is slight but increasing evidence that as the chorion develops it takes to itself the production of progesterin or a similar hormone which doubtless maintains integrity of the maternal portion of the placenta.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning April 5

Berkshire

Thursday, April 9, at 4 30 P. M., at the House of Mercy Hospital, Pittsfield. Subject: Diseases of the Liver — Hepatitis and Painless Jaundice. Problems in Diagnosis and Treatment. Instructor: E. S. Emery, Melvin H. Walker, Jr., Chairman.

Bristol North

Wednesday April 8, at 7 30 P.M., at the Morton Hospital, Taunton. Subject: Kidney and Bladder Diseases A and B (Surgical)—Hematuria Its Significance in Surgical Diseases of Kidney and Bladder Prostatism and Related Diseases Cystitis and Pyelitis. Instructor: Richard Chute. Arthur R. Crandall, Chairman.

Bristol South (New Bedford Section)

Friday April 10 at 4 00 P.M. at the St. Luke's Hospital, New Bedford. Subject: Pediatrics (Medical)—The Neonatal State. Instructor: L. W. Hill. Harold E. Perry, Chairman.

Norfolk*

Friday April 10 at 8 30 P.M., at the Norwood Hospital, Norwood. Subject: Dermatology—Ten Common Skin Diseases—Diagnosis and Treatment. (1) Impetigo Contagiosa (2) Scabies (3) Acne Vulgaris, (4) Psoriasis and Seborrheic Dermatitis (5) Epl. dermatophytosis (6) Herpes Simplex and Zoster (7) Eczema, (8) Erythema Multiforme (9) Verruca Vulgaris and (10) Dermatitis Medicamentosa and Dermatitis Venenata. Instructor: E. L. Oliver. H. B. C. Riemer, Chairman.

Worcester (Milford Section)

Wednesday April 8 at 8 30 P.M. at the Milford Hospital, Milford. Subject: Kidney and Bladder Diseases B (Surgical)—Prostatism and Related Diseases. Cystitis and Pyelitis. Instructor: S. B. Kelley. Joseph I. Ashklus, Sub-Chairman.

The Course previously given at the Faulkner Hospital has been combined with the group at the Norwood Hospital.

MASSACHUSETTS LEGISLATIVE NOTES

HOUSE BILL 34

The Senate has passed House Bill 34 with three amendments which are as follows:

In House

Amend the bill by adding after section 3 the following new section—"Section 3 For purposes of examination and registration osteopathic schools rated as A schools by the American Osteopathic Association shall have the same standing before the board as A schools so rated by the American Medical Association.

In Senate

Add at the end of section one the following—"An applicant aggrieved by the refusal of the board to approve a medical school under this section shall be entitled to have the reasonableness of such refusal reviewed by a justice of the superior court, whose decision shall be final."

In Senate

In section 1—striking out in line 15 the words

"the board and inserting in place thereof, the words "a board consisting of the Secretary of the Board of Registration in Medicine the Commissioner of Education, and the Commissioner of Public Health.

These amendments leave the more important features of the bill operative. The bill now goes to the House for concurrent action and if passed by the House will be presented to the Governor. It has had a long and stormy passage.

MISCELLANY

AFFAIRS IN CONNECTICUT

A COMMISSION TO STUDY LAWS RELATIVE TO AUTOMOBILE ACCIDENTS

A temporary commission has been appointed in Connecticut to study financial responsibility laws as they relate to automobile accidents. This commission consisting of Motor Vehicle Commissioner Michael A. Connor Insurance Commissioner John C. Blackall and Superior Court Judge Frank P. McEvoy has been meeting informally with various groups affected by and interested in these laws. On March 9 1935 representative physicians from the eight different counties were given a hearing by this commission and on this occasion it was learned that Connecticut hospitals are losing money caring for persons injured in automobile accidents with no means of paying for their treatment. The commission was informed that in many of these cases where the responsible person carries no liability insurance the hospital has no means of collecting its costs. The physicians present also impressed upon the commission the fact that members of the profession caring for emergency cases frequently find themselves unable to collect for services rendered.

There is a very strong feeling among the medical profession in Connecticut that the present laws relating to financial responsibility in automobile accident cases are entirely inadequate. Advocates may be found of compulsory liability insurance for all automobilists as exists in Massachusetts. Others are in favor of the establishment of a state fund maintained by taxation to be used to meet hospital bills and physicians fees in such cases.

PNEUMONIA MORTALITY

The death rate from pneumonia in Connecticut during the last six years has been consistently lower than at any time as far back as 1885. For 1935 the pneumonia death rate was 65.2 per 100,000 population. The lowest rate during the past fifty years was attained in 1934 that of 6.9. The 1935 rate was the second lowest with only 113 deaths. The highest point was reached in 1918 when influenza was epidemic in this country and in Europe.

The director of the Bureau of Preventable Diseases of the State Department of Health believes that the use of pneumonia serum has had some of

fect in reducing the death rate, though just how much he was unwilling to estimate

New Britain has experienced an epidemic of scarlet fever so severe that it was considered wise to close the schools.

PROBLEMS IN CONNECTION WITH THE FLOOD

Hartford and neighboring towns and cities along the Connecticut River, after experiencing the worst flood in their history, now face the possibility of an epidemic as the waters subside. The State Commissioner of Health has recommended that all persons working in flooded areas throughout the State be immunized against typhoid fever. The Hartford Board of Health has already started this preventive treatment.

The public water supplies throughout Connecticut during the flood have remained unimpaired, although at one time it was believed that the town of Cromwell had suffered pollution of its reservoir. This water supply was later proved by tests to be safe. A food shortage is not likely since highway communication and rail communication to the southwest have remained open.

In Hartford, to prevent the spreading of respiratory diseases and to give first aid treatment, volunteer physicians have been assigned to various schools where the refugees are housed. These physicians work in two-hour shifts throughout the day and until midnight, the remainder of the twenty-four hour period being covered by physicians on call. The Hartford Dispensary has remained open day and night, including Sunday, and has been covered by its own volunteer staff of physicians also working in two-hour shifts. Private practice has been greatly disrupted by the absence of electricity, phone service and the difficulties of transportation. For several days, while without an adequate supply of electricity, the various hospitals of Hartford were forced to limit their surgical work to emergencies.

CONNECTICUT NEWS

G Mansfield Craig, M.D., of Haddam has been appointed medical examiner of that town by Colonel L. A. Smith.

Louis M. Allyn, M.D., of Mystic has resigned as a member of the board of trustees of the Mystic Oral School for the Deaf. To fill this vacancy Governor Cross has appointed Hugh F. Lena, M.D., of New London.

The school is a State institution for the care and training of deaf children. Although Dr. Allyn has resigned from the board of trustees he will continue as physician at the school. Dr. Lena is appointed for the unexpired portion of Dr. Allyn's term ending July 1, 1936, and for the full term of three years from that date. Dr. Lena is a graduate of Dartmouth, 1912 and Johns Hopkins University School of Medicine, 1916. Since his discharge from the U. S. Navy in 1919 he has operated his own private hospital in New London.

RECENT DEATH

CROWE—WILLIS HANFORD CROWE, M.D., of 409 Whitney Avenue, New Haven, Connecticut, with an office at 59 College Street, died at his home, March 24, 1936.

Dr. Crowe was born in 1873 and graduated from the College of Physicians and Surgeons of New York in 1895. He had served on the surgical staff of St. Raphael's Hospital for many years.

His widow, Mrs. Grace McDonald Crowe, a son, Willis M. Crowe, of Worcester, and a daughter, Mrs. Schuyler Gillespie, survive him.

OBITUARY

TRACY—DWIGHT WALLACE TRACY, M.D., fifty-two years old, one of Hartford's leading dermatologists, died at his home in West Hartford, Sunday, March 22, 1936. He had been ill with heart disease for several months and in December, 1935, was obliged to relinquish his practice.

Dr. Tracy was born in Hartford, May 28, 1883, son of the late D. W. Tracy, for many years a prominent pharmacist of that city. He received his elementary education in Hartford, was graduated from Yale University in 1904 and from Johns Hopkins University School of Medicine in 1908. After studying abroad he served an internship at the Hartford Hospital. During the World War Dr. Tracy was contract surgeon for the Students' Army Training Corps at Trinity College, Hartford, being commissioned major. For eleven years he served as medical inspector for the Hartford Board of Health prior to the war. Before his retirement from practice Dr. Tracy had served for many years on the staffs of the Hartford, Hartford Municipal, Litchfield County, Canaan, Middlesex, and Charlotte Hungerford (Torrington) Hospitals. He was a thirty-second degree Mason and a Past Master of Hartford Lodge, No. 88, A. F. & A. M. A member of the Hartford Medical Society, the Hartford County Medical Association, and the Connecticut State Medical Society, he also belonged to several clubs including the University Club of Hartford, the Yale Graduate Club of New Haven, and the Yale Club of New York City. He was active in the work of Christ Church Cathedral of which he was a member.

Dr. Tracy is survived by a widow and three children. The funeral was held from his home on March 24, 1936, several of his friends in the profession serving as bearers.

THE ELECTION OF DR. SHIELDS WARREN

At a recent meeting of the American Society for Experimental Pathology, Dr. Shields Warren of Boston was elected Secretary-Treasurer.

According to a report in the *New York Times*, Dr. Warren made some valuable suggestions on the irradiation of cancers by x-rays and the gamma rays of radium. Experimenting on rats, Dr. Warren found that cancer cells fail to multiply at the normal rate within an hour and a half after a radium

treatment. The lowest point of reproduction is reached from two to ten hours after irradiation. The cancer cells begin to multiply again after that time but at only a third of the old rate for some seventy two hours.

APPOINTMENT OF NEW MEMBERS TO THE HARVARD FACULTY

James R. Lingley of the Massachusetts General Hospital Boston, Mass. B.A. Acadie University N.S., 23 M.A. Ibid. 24, M.D. Harvard 25 appointed Roentgenologist in charge of the X Ray work of the Harvard Hygiene Department until September 1 1936. He is now Assistant Roentgenologist at the Massachusetts General Hospital, and Roentgenologist at the McLean Hospital, Waverley and at the Norfolk Prison Colony Mass.

MARCH 1 TO SEPTEMBER 1 1936

Professor Julian H. Capps of Berea College Ky. A.B. Illinois 13 A.M. Princeton 14 appointed Research Fellow in Chemistry. Professor Capps is on leave from Berea College and while at Harvard will do research in collaboration with Professor Gregory P. Baxter of the Harvard Chemistry Department.

James A. Kennedy of the Peter Bent Brigham Hospital Boston Mass. A.B. Vanderbilt University 31 M.D. Ibid. 34 appointed Research Fellow in Medicine.

FOR ONE YEAR FROM APRIL 1 1936

Robert B. Hightower of the Childrens Hospital Boston Mass., S.B. Mississippi State College 27 M.D. University of Virginia 32, appointed Instructor in Child Hygiene and Pediatrics in the Harvard Medical School and School of Public Health.

APPOINTMENTS TO THE BOARD OF SCIENTIFIC DIRECTORS OF THE ROCKEFELLER INSTITUTE

The Board of Trustees of The Rockefeller Institute for Medical Research announces the election of Dr. Walter Bradford Cannon and Dr. George Hoyt Whipple as members of the Board of Scientific Directors.

CHRONIC DISEASE*

"Chronic disease is becoming a major public health problem. This is largely due to the change in the composition of the population. In Massachusetts in 1850 31 per cent of the population died after the age of forty. In 1934 78 per cent. The factors behind the ageing of the Massachusetts population are improved public health activities which have lessened the number of deaths in early infancy and young adulthood the declining birth rate which tends to increase the average age of the population and the decreased immigration which lowers our population in the middle age groups.

The ratio of the number of individuals in the productive age group (20-60) to the nonproductive age group (over 60) has declined since 1870 from 7 to 1 to 5.4 to 1. On the other hand while the total expectation of life is considerably greater than at any other time in our history there has been practically no change in the expectation of life of individuals who arrive at the age of fifty. The average age at time of death of those individuals is slightly less than it was two generations ago.

With more people coming into the late adult age groups and with no improvement in the diseases most common in these age groups a problem both from an economic and a humanitarian standpoint arises. The ever decreasing number of individuals in the wage-earning groups has an ever increasing number of completely dependent individuals in the nonproductive age groups.

The costs of chronic disease are much higher than those of acute illnesses as the duration is long and the care needed in many cases is considerable. A ten-year period of complete disability with chronic rheumatism entails great suffering on the part of the individual as well as an economic burden on the part of the family. The problem however would not be nearly so acute if all chronic disease were confined to the over-sixty group. Instead a large part of it is occurring in the productive ages.

"During 1929-31 the State Department of Public Health made a survey of chronic disease in fifty one cities and towns in Massachusetts. From the records obtained we estimated that 21 per cent of the population between forty and fifty were suffering from chronic disease. Many of these individuals were still able to work as the disease had not progressed far enough to warrant invalidism. None of them however could do as good work as if they had been free from chronic disease.

Chronic disease will probably never be completely eradicated but if its onset could be delayed until late adult life an immediate improvement in conditions would be apparent not only in the individual and his family but also in the general community because he would be an asset rather than a liability. The solution probably lies in—first, a better knowledge of the various chronic disease conditions; secondly, better hygiene on the part of the people throughout childhood and middle life; and thirdly, frequent consultations with family physicians at least, when slight deviations from normal occur and as an optimum periodic health examinations while still well. There is considerable evidence to show that many of the chronic disease processes are influenced by faulty hygiene. Improvement in this direction may prolong the onset of many of these diseases. A large part of the population does not seek medical advice even when it is aware of abnormalities of function. Many diseases could be arrested in their early stages if the public were better educated in making use of available medical facilities and if the physicians were better educated in the recognition and study of minor deviations from the normal.

*Part of a free public lecture by Dr. Herbert L. Lombard, Director, Division of Adult Hygiene, Massachusetts Department of Public Health given Sunday afternoon, March 2, at the Harvard Medical School.

"Inasmuch as many of the procedures incidental to the establishment of a diagnosis, such as x-ray, metabolism tests, blood chemistry, etc., require considerable outlay on the part of the patient and expensive equipment on the part of the physician, it naturally follows that every physician has no such resources available for every individual. Some method must be inaugurated whereby every physician will have at his disposal adequate laboratory facilities for patients of low and moderate means. Many suggestions have been made as to how this can best be accomplished. It is my feeling that government money should be used to help both the physician and his low-income patient to obtain

these services. It should be possible for the physician to have access to free x-ray, metabolism tests, etc., when the need for them arises. If this were possible, much of the criticism of the costs of medical care would be removed.

"Such a program was inaugurated for cancer in this State ten years ago. Any person unable to pay receives as much x-ray diagnostic work as is needed and any other processes necessary for the establishment of a diagnosis and for subsequent treatment. This plan has worked admirably in cancer. It might well be extended to other diseases."

COMPARISON OF DISEASE INCIDENCE IN CONNECTICUT WITH 1935 AND SEVEN YEAR AVERAGE

MONTH ENDING FEBRUARY 29, 1936

Remarks No cases of Asiatic cholera, glanders, plague or yellow fever during the past seven years.

THE PROBABLE APPOINTMENT OF DR. PARRAN

President Roosevelt has nominated Dr. Thomas Parran, Jr. to succeed Dr. Hugh Cumming as Surgeon General of the United States. There is every reason to expect that this will be confirmed both because Dr. Parran was appointed by the President as Health Commissioner of New York State and because his administration of the State Health Department was most satisfactory.

Although the administration of the Public Health Service by Dr. Cumming has been generally endorsed there is abundant reason to believe that the quality of public service in this department will not diminish under Dr. Parran's direction.

This appointment is just recognition of an honorable and efficient public servant.

MORTALITY RATES FOR 1936

So far as the 'Weekly Health Index' of the Bureau of the Census applies to the United States it seems to show that the mortality rates for February and March 1936 are well above those of 1935. The figures are based on a population of thirty seven million inhabitants of eighty five cities and are for February more than a full point per 100,000 above the rates for last year.

Climatic conditions have been trying this year and may have had an effect on the mortality rates.

CORRESPONDENCE

PUERPERAL DEATHS

Harvard University
School of Public Health

March 18 1936

Editor *New England Journal of Medicine*

The need for care in the presentation and interpretation of statistical data has become more generally recognized by physicians in recent years but medical literature continues to include examples of the misuse of such data. It would seem desirable to call attention from time to time to one or another of the statistical errors which the physician is likely to encounter in order to keep writers constantly on their guard. With this in mind I am submitting a chart and citing a recent example from your *Journal* which shows rather vividly the kind of error which may result from the incorrect choice of a basis for the estimation of a death rate.

In your issue of October 10 1935 an article dealing with Changes in Maternal Mortality and Their Significance appeared to show that there has been a sharp decline in maternal mortality in Massachusetts during recent years and attributed this primarily to the efforts of the medical profession. Unfortunately the author failed to take into account the fact that only a small portion of the total population are potential candidates for death from puerperal causes and that the percentage of these has been falling rapidly in recent years. The accompanying chart shows in the curve at the top the

rapidity with which the birth rate has been falling in Massachusetts since 1920 and the middle curve shows that the number of puerperal deaths per 100,000 population has been falling with almost equal rapidity. This is the curve upon which the principal conclusions in the article referred to were based.

Assuming that a woman cannot die from causes associated with pregnancy without first becoming pregnant, other things being equal the number of puerperal deaths will vary directly with the number

MASSACHUSETTS

Inclusive of stillbirth and making proper deductions for plural births.

of pregnant women in the community. We have no record of the actual number of pregnancies occurring in the State during each year but we do know the number of stillbirths and live births. If we assume that practically all deaths reported as puerperal are associated with these we may add together the reported stillbirths and live births correct for multiple births, and use the resulting figure as the basis for a maternal death rate. The curve shown at the bottom of the accompanying chart was obtained in this way. Owing to the fact, however, that only live births are reported with absolute accuracy it has become customary to use as a maternal mortality rate one that is related to live births alone. This curve is also shown and is almost identical with the one corrected for stillbirths and multiple births. It may therefore be assumed that the customary maternal mortality rate based upon live births portrays quite accurately any changes in the number of maternal deaths which occur per thousand pregnancies. This rate plots out, as shown in the chart, as an almost straight and undescending line and only in the year 1934 can it be inferred that improvement is suggested by the figures. The ar

ticle therefore entirely loses its point for it explains an assumed improvement which is in reality non-existent

It has seemed worthwhile to present this chart as an example of one of the errors to be avoided and I trust that you will find space for its publication

HAROLD C. STUART, M.D.

PERMANENT WAVES AND HAIR DYE

Editor, *New England Journal of Medicine*,

For the last two years a patient of mine has been very much annoyed and chagrined by the results of her "permanent waves." This white-haired lady allows herself only one "permanent wave" each year and on the last two occasions she has returned to her family more or less disguised by the slate color of her hair. Her chief lament has been that she feared her friends would consider that she had been foolish enough to allow her hair to be dyed.

Such an experience has been unique in my practice and as I have felt that perhaps idiosyncrasy played the leading rôle in these mishaps I have said nothing in print about them. My theory has been, however, that the patient has been using for some time a hair lotion containing mercury and that owing to the great heat employed in the "permanent" waving of the hair or to the unknown patented solution which all hair-dressers use prior to the application of the heat, the normal sulphur content of the hair has become susceptible to the mercury of the hair lotion and the resultant color has been due to the deposit of the black sulphide of mercury. Unfortunately, this discoloration has proved to be a fast dye yielding to no decolorizer which I have dared to use on this delicate white hair. The lapse of time each year has restored the normal color.

One reason for this letter to the *Journal* is due to the fact that my experience has proved not to be unique, for Drs. A. M. H. Gray and R. Klaber have published on pages 97-99 of the *British Journal of Dermatology and Syphilis* for February 1936 a similar observation in which the hair became a brown black. Dr. Gray states that the unknown solution used by English hairdressers to prepare the hair for the "permanent" waving contains ammonia. Dr. Gray further writes that he has found in the literature only one analogue, that described by K. Philipsen (*Ugeskr. f. Læger* 95:746 [June 29] 1933—*Zentralbl. f. Haut* 46:199, 1933).

My second reason for this letter, following the experience now of three observers, is to warn physicians who are about to prescribe to white-haired ladies mercury-containing hair lotions to tell these patients that such a lotion is incompatible with "permanent waving" and that if they desire such treatment from a hairdresser they must suspend the use of such a lotion probably, for at least two months.

CHARLES J. WHITE, M.D.

259 Marlborough Street,
Boston, Mass.

A NEW METHOD OF MEDICAL ILLUSTRATION

Editor, *New England Journal of Medicine*,

During the past year a new method of illustration has been found successful for demonstrating the steps of surgical procedures or for summarizing the steps in the treatment of special cases. The method of applying color to the commercial product of translite paper for medical use was developed by me in this Clinic. A drawing or photograph is so colored and illuminated as to give a more realistic and effective result than has been possible with the usual black and white illustration.

The basis of the illustration is a half tone drawing. A photograph of the drawing is made directly on to translite paper (Eastman). The translite paper, being sensitive on both sides, takes too dark a print on the front and too light a print on the back. When a light is placed behind the print the correct value is obtained. Color is applied to the back of the print. Transparent oil colors are used. When the print is shown in a dimly lighted room the color is visible from the front.

Translite Exhibit Cabinet

In making the translite print the photographer should take care to make the print light enough so that when the color is applied to the back of the print the shading will be light enough and the color effect will not be "muddy."

The oil paint is applied to the print in the manner of coloring photographs. The best result is obtained by coloring the print over a ground glass in front of a daylight electric light bulb. For ease of handling the print while coloring it is convenient to mount it on a piece of cardboard which has a hole cut out the exact size of the drawing. Adhesive tape may be used to hold the margins of the print to the cardboard frame. The thickness of the cardboard enables the print to be handled and laid color side down without allowing anything to touch the color side.

When a series of prints are exhibited they may be shown in an arrangement similar to that used for x-ray films. Pieces of clear glass and ground glass with the print between them are held in place by a series of frames. The enclosed space behind the illustrations contains the lights. Frosted day light electric bulbs are satisfactory. If the drawings or photographs are matted with dark paper the artistic effect is better. If the mat is made large enough a space may be cut away for a title which is also made on the translucent paper. The mat helps in keeping all light from within the cabinet from showing through accidental cracks between the print and the frame.

Color used in this manner makes drawings or photographs more graphic. When drawings, photographs and x-rays are thus assembled the arrangement is very satisfactory for study by a group of people.

PERIARTERITIS NODOSA

March 20 1936

Editor *New England Journal of Medicine*

In the March 19 issue of *The New England Journal of Medicine* there appeared an extremely interesting report from the Case Records of the Massachusetts General Hospital. It was a fatal case of (probable) periarteritis nodosa in which skin changes were a prominent feature. The latter included vesicles, pustules, scaly erythematous patches, swollen and blotchy lesions and nodules. In the discussion the belief was expressed by several of the physicians present and by the pathologist in particular that the skin lesions had no relation to the underlying disorder.

It is therefore pertinent to present the following. Crosti A. (Glor. Ital. di dermat. e sif. 76 15 Feb. 1935) described a case of periarteritis nodosa in a five-year-old boy in whom the skin changes were very striking. They were composed mainly of areas of polymorphous erythema and nodular infiltrates the latter varying in size from a millet seed to a pea. Crosti also called attention to the fact that it is necessary to recognize the cutaneous and subcutaneous symptomatology (which may be comprised of infiltrative erythema, hemorrhages, nodules, necrosis or elephantiasis) not infrequently present in periarteritis nodosa. The reason is obvious especially in cases not fatal and in those in which a biopsy is impossible.

Another recent case was that reported by F. Goldschlag and A. von Chwallibogowski (Arch. f. Dermat. u. Syph. 171 8*2 [Aug. 14] 1935). The diagnosis of periarteritis nodosa was confirmed histologically. The most striking changes of the entire clinical picture were those in the skin. The latter presented livid quarter-dollar-sized areas, papules, articular effluorescences, subcutaneous nodules and livedo racemosa.

In a very recent article L. Motley (J. A. M. A. 105 898 [Mar. 14] 1936) called attention to the fact that skin lesions not infrequently appear in periarteritis nodosa and take the form of subcutaneous hemorrhages, urticaria and in particular purpura resembling Schönlein's disease. One of his cases presented erythematous purpuric-like lesions and subcutaneous nodules.

If one is to believe the assumption of some of the leading dermatologists that periarteritis nodosa is a symptom complex similar to erythema nodosum-like and erythema multiforme-like conditions due to various etiologic agents such as drugs, infections, etc., then the skin lesions present should naturally be a prominent and striking feature of the entire picture.

J. L. GAUDET, M.D.

483 Beacon Street
Boston, Mass.

RECENT DEATH

BARNES—IDA F. BARNES, M.D., a graduate of the Boston University School of Medicine in 1893, died at her home in Beverly, Massachusetts, March 28, 1936. Dr. Barnes was born in New York, the daughter of Hobart and Alice Barnes. After graduating in medicine, she practiced for a time in Boston.

NOTICES

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday, April 9, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr. Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physics in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12 staff rounds will be conducted by Dr. Christian.

EXAMINATION OF CANDIDATES FOR APPOINTMENT TO THE PUBLIC HEALTH SERVICE

A board of commissioned officers will meet at the U. S. Marine Hospital, Boston, Mass., at 10 A.M. April 13, 1936, for the purpose of examining candidates to determine their eligibility for appointment to the grade of Assistant Surgeon in the Regular Corps of the Public Health Service.

BUREAU OF MEDICAL RELATIONS WITH FOREIGN COUNTRIES AT THE FACULTY OF MEDICINE—PARIS, FRANCE

Announcement has been made of the existence of a Bureau of Medical Relations with Foreign Countries (Bureau des Relations Médicales avec l'Etranger) by the Faculty of Medicine in Paris. More students and physicians are able to obtain any in-

formation they desire concerning postgraduate courses of hospital services

Foreign students or physicians should communicate with the Bureau of Medical Relations at the Faculty of Medicine in Paris and announce their arrival, a cordial welcome will be extended to them

AMERICAN MEDICAL GOLFERS PLAY IN KANSAS CITY, MONDAY, MAY 11

The American Medical Golfing Association will hold its twentysecond annual tournament at the Mission Hills Country Club and the Kansas City Country Club in Kansas City on Monday, May 11, 1936

To accommodate comfortably the large entry which is anticipated, the Kansas City Committee has arranged play over two very fine courses which touch corners the Mission Hills Country Club and the Kansas City Country Club. Their club houses are only one mile apart and ample transportation between the two has been arranged. Dinner for all players will be served in the Mission Hills Club House.

Seventy Trophies and Prizes will be awarded

There are 1,150 A. M. G. A. members. Every state of the Union is represented.

APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the A. M. G. A. The Executive Secretary, Bill Burns, 2,020 Olds Tower, Lansing, Michigan, will furnish application blanks.

UNITED STATES CIVIL SERVICE EXAMINATIONS

Clinical Director (Female), \$5,600 a Year

Director of Laboratories, \$5,600 a Year

Associate Psychotherapist (Female), \$3,200 a Year

Saint Elizabeths Hospital, Washington, D. C.

Applications must be on file with the United States Civil Service Commission at Washington, D. C., not later than April 20, 1936.

Duties—Clinical Director (Female)—As general administrator of a major division of a psychiatric hospital, to direct the medical and nursing personnel in connection with the psychiatric examination, care and treatment of more than 1,800 women patients.

Director of Laboratories—As general administrator of the research activities in psychiatry, particularly from a laboratory standpoint, to direct the laboratory units in pathology, chemistry, bacteriology, and related groups, to conduct scientific conferences, and to participate in the various courses of instruction given to physicians and students.

Associate Psychotherapist (Female)—To conduct research and investigational work relative to the causes, symptomatology, and mechanisms of mental diseases, to treat individual patients by psychotherapy.

Applicants must have been graduated from a medical school of recognized standing with a degree of M.D.

REPORTS AND NOTICES OF MEETINGS

NEW ENGLAND HEART ASSOCIATION

The February meeting of the New England Heart Association was held at the Beth Israel Hospital on the evening of February 3, 1936.

The first paper of the evening was "A Case of Coronary Occlusion with Interesting Features," by Dr. Harry B. Levine. A sixty-one year old man with a history of angina pectoris, and a high blood pressure, had a typical attack of coronary occlusion. The following day his apical rate rose to 180, there was a slight variation in the intensity of the first sound at the apex and vagal pressure had no effect. A diagnosis of ventricular tachycardia was made. Under quinidine therapy the rate dropped to 120. About two weeks later he developed auricular flutter with an auricular rate of 400, and ventricular rate of 200. Under digitalis the ventricular rate became 100. In spite of treatment, congestive failure set in about one month later and he had attacks of paroxysmal dyspnea. Several diuretics failed to help him and two years later he developed attacks of paroxysmal auricular fibrillation which were controlled by quinidine. From the onset of congestive failure, he received eighty-one injections of salyrgan and mercupurin. Recently a suppository form of mercurin has been used with marked diuresis, but it is sometimes necessary to use two suppositories in order to secure satisfactory results.

The second paper was on "The Evaluation of Medicinal Treatment of Angina Pectoris" by Dr. Joseph E. F. Ruseman. The efficacy of medicinal treatment in angina pectoris was evaluated in twenty-five patients by means of the standardized exercise tolerance test and by observing the effect on the clinical frequency of attacks. The latter method by itself was of little value, as the clinical history was influenced by many factors, such as the psychological effect of treatment, spontaneous variations in the severity of the disease, and changes in the physical and emotional activity of the patient. According to the clinical history, as many patients were benefited by placebo pills as by any other medication. It is evident that an objective measure of the clinical response, such as the standardized exercise tolerance test, is necessary. Improvement due to medication is indicated by an increase in exercise tolerance which disappears when the medication is omitted and placebo medication is substituted, and which reappears only when the medication is again given, even if the appearance of the drug is disguised. According to these criteria, no patient showed improvement following placebo pills, sodium bicarbonate, potassium iodide or oral tissue extract. About one-third of the patients failed to improve following any of the fifteen different drugs. Slightly less than

one-half showed improvement following either aminophyllin (grains 8 four times daily) or quindine sulphate (grains 5 four times daily). About one-third were benefited by erythral tetranitrate codeine sulphate or atropine sulphate, and about fifteen per cent were helped by sodium nitrate theophyllin calcium selcylete or small doses of dinitrophenol (grains 1½ daily). Digitalis caused a marked increase in pain in about one-half of the patients.

Complete disappearance of cardiac pain was rare. Aminophyllin caused the greatest increase in exercise tolerance 10 to 100 per cent, the remaining effective drugs allowed the patient to increase his work by about 20 to 50 per cent. For the routine treatment of angina, aminophyllin and quindine sulphate offer the greatest possibility of giving benefit.

The third paper was on "Studies on the Effect of Nitroglycerine on Angina Pectoris" by Dr Morton G. Brown. A group of patients with angina pectoris were given nitroglycerine gr 1/500 according to two procedures. Patients were instructed to place one tablet under the tongue every hour during the day. In order to determine how soon the action began and how long it acted, the patients exercise tolerance was determined at various time intervals after placing a tablet under the tongue. In about one-third of the patients the effect was marked and prolonged, lasting nearly an hour. In another third the effect was less prolonged and less striking. In the remaining patients it had no effect. The clinical results paralleled the exercise tolerance tests, in that those who showed the marked effect were free of angina while taking nitroglycerine at hourly intervals. Those in whom the action of nitroglycerine was of shorter duration derived benefit when they took the drug before that effort which usually precipitated the attack. The small dose of 1/500 gr of nitroglycerine was found nearly as effective as the usual dose of 1/100 gr and was unattended by untoward reactions whereas many of the patients receiving 1/100 gr of nitroglycerine had reactions.

The fourth paper was on "The Incidence of Coronary and Hypertensive Heart Diseases in Different Population Groups" by Dr Louis Silver. A study of the incidence of angina pectoris and coronary occlusion among the patients with arteriosclerotic and hypertensive heart disease of the Massachusetts General Hospital, The Baker Memorial Phillips House and the Beth Israel Hospital representing the several different strata of society showed that the Jewish patients fairly outnumbered other races in the incidence of these diseases. In the Beth Israel Hospital there is an incidence of 56 per cent. It was shown that the incidence of angina pectoris and coronary occlusion is somewhat more frequent among Jewish immigrants than natives and less common among Italian immigrants. The total number of patients with arteriosclerotic heart disease with or without coronary occlusion did not fluctuate greatly in these groups indicating that the process of degeneration works about equally in the different groups. It is in the early stormy and malignant manifesta-

tion of arteriosclerotic heart disease where the fluctuations are marked. These two coronary conditions occur twice as frequently in men as in women.

The fifth paper was "The Cardiac Output in Patients with Congestive Failure after Total Thyroidectomy" by Dr Mark D. Altschule. The cardiac output, vital capacity, pulmonary circulation time, venous pressure, and arterial pressure were measured in twenty-three patients before and after total thyroidectomy. The work of the heart was calculated from the cardiac output by means of the formula of Evans. It was found that the cardiac output and work diminished as the basal metabolic rate fell after operation. The cardiac output decreased about 10 per cent more than the basal metabolism especially in patients without congestive failure so that the arteriovenous oxygen differences increased. This was less striking in patients operated on for the relief of congestive failure since in such cases the cardiac output was low before operation. The relief experienced by the patients after operation was associated with a marked diminution in the work of the heart. In patients operated on for congestive failure, the cardiac output decreased to a level below which it merely balanced the oxygen consumption, thus giving such patients a margin in which to increase their cardiac outputs in response to activity.

The sixth paper was on "A Clinical and Pathologic Study of Aortic Stenosis" by Dr Louis Wolff. This presentation is based primarily upon a study of sixteen cases of aortic stenosis without other valve lesions proved at autopsy. The youngest patient in this group was forty years old. Syncope occurred as a single episode in only one patient of this series. Angina pectoris occurred in two patients in one of whom there was no evidence of coronary artery disease at postmortem examination. There was a question of angina pectoris in a third patient. There were no sudden deaths. Considerable loss of weight occurred in seven of these patients, usually beginning before the onset of cardiovascular symptoms. The description of the pulse, the pulse pressure, the aortic second sound, and a systolic thrill at the aortic area cannot be depended upon in making the diagnosis of aortic stenosis on account of the infrequency with which these signs occur. The systolic thrill, however, may be regarded as the most significant sign, and if especial care and technique are used the thrill may be found in a high percentage of the cases.

The only constant sign occurring in aortic stenosis is a loud systolic murmur at the aortic area, and its only constant characteristic is transmission upwards into the vessels of the neck. This sign will be found in every patient with aortic stenosis unless there is a state of collapse or acute myocardial failure such as may follow coronary thrombosis and cardiac infarction. If we exclude cases of aortic stenosis a systolic murmur at the aortic area is found in 10 per cent of all patients who at autopsy show some form of heart disease. This murmur however is not always produced at

the aortic valve. If the murmur is produced at the aortic valve and is transmitted at all, it is to be expected that the direction of its transmission will be in the direction of the blood flow, i.e., upwards into the vessels of the neck. In a group of over 160 autopsied cases such a murmur was found in aortic stenosis, recognized by the pathologist from fusion of the aortic cusps or by measurements of the aortic ring, in hearts in which the aortic leaflets were sufficiently sclerosed and stiffened to interfere with the free mobility of the cusps causing an impediment to the flow of blood from the ventricle into the aorta, thus constituting a functional aortic stenosis, and in luetic aortic dilatation. When the characteristic murmur is produced, the dilatation of the aorta is sufficiently great so that its recognition by physical examination or fluoroscopy is easy. All the evidence available from a study of this group and by comparison with a similar group of patients with aortic stenosis with other valve lesions proved at autopsy indicates that the etiology of the aortic stenosis in at least most of these cases is arteriosclerosis. No evidence could be found that rheumatic infection or other infections played a rôle in this particular series.

The seventh paper was "Calcified Stenosis of Aortic Valve" by Dr. M. J. Schiesinger. Sixteen cases of heart disease with calcified stenosis of the aortic valve without any other valvular lesions were analyzed from the viewpoint of sex, age, heart weight, amount of arteriosclerosis of the coronaries and of the aorta, chronic passive congestion of the viscera, degree of terminal congestive failure and other causes of death. In eleven of the cases, the valve ring was calcified, the leaflets were fused, thickened, and calcified, and shelf like, and the opening was a slit, the others showed a less marked lesion. Only three of the patients were women, all of whom died of another disease. The youngest patient was forty and the oldest seventy-eight, and the ages were uniformly distributed in between. No correlation could be found with the degree of coronary sclerosis or arteriosclerosis of the aorta. One heart weighed 300 grams and one 840 grams. The others varied between 400 and 760 grams. The patient with the smallest heart died at fifty one of carcinoma of the stomach with no evidence of cardiac failure. The largest heart was from the youngest patient (forty years) who showed much chronic passive congestion of the viscera and died an uncomplicated congestive failure death. Only two other cases showed any appreciable chronic passive congestion of the viscera. However, in nine of the cases, congestive failure was an important part of the terminal picture. Death in the other cases was due to causes extrinsic to the heart.

It was concluded that calcified aortic stenosis was a lesion rather well tolerated by the heart and usually well compensated for by hypertrophy of the left ventricle. When congestive failure sets in, the prognosis is poor. Calcified aortic stenosis can be considered an independent pathologic entity of the nature of localized arteriosclerosis. The mechanism

of the localization on this valve is no more evident than is the mechanism of the localization of cerebral or coronary arteriosclerosis.

The eighth paper was "A Summary of Clinical Experience in the Treatment of Chronic Heart Disease by Total Thyroidectomy" by Dr. Herrman L. Blumgart. The results of total thyroidectomy at twenty-six clinics were summarized. Of the 185 patients whose condition was evaluated, 121 patients suffered from congestive failure, sixty-four from angina pectoris. Sixty-three per cent of the patients with congestive failure showed either excellent or moderate improvement, 18 per cent slight improvement, and 18 per cent no improvement. Of the sixty-four patients with angina pectoris, 86 per cent showed either excellent or moderate improvement, 9 per cent slight improvement, and 5 per cent no improvement. The operative mortality was 4.7 per cent. It was particularly encouraging to note that a large proportion of the patients had shown these results either one or two years after operation or two to three years after operation.

WILLIAM HARVEY SOCIETY

The next meeting of the William Harvey Society will be held Friday, April 10, in the Auditorium of the Beth Israel Hospital, Boston, at 8:00 P.M.

PROGRAM

Speaker Dr. Elliott C. Cutler, Harvard Medical School

Subject "War Surgery"

Chairman Dr. Horace Binney, Professor of Surgery, Tufts College Medical School

AMERICAN HEART ASSOCIATION, INC.

The Twelfth Scientific Session of the American Heart Association will be held on Tuesday, May 12, 1936, from 9:30 to 5:30 P.M., at Hotel Phillips, Kansas City, Missouri. The program will be devoted to Cardiac Insufficiency.

GREATER BOSTON MEDICAL SOCIETY

Time Thursday, April 9, 1936, 8:15 P.M.

Place Auditorium, Beth Israel Hospital, Boston.

Results of Total Thyroidectomy in Twenty-Six Other Clinics J. E. F. Riseman, M.D., Beth Israel Hospital

A Social Study of Patients with Chronic Heart Disease Treated by Total Thyroidectomy Miss Ethel Cohen, Director of Social Service, Beth Israel Hospital

Meeting open to physicians, medical students, social service workers and nurses

H. L. LINENTHAL, M.D., *President*,

D. B. STEARNS, M.D., *Secretary*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, April 14, at 8:15 P.M.

PROGRAM

Presentation of Cases

Medical Inheritance By Dr. Reginald Fitz.

Medical students and physicians are cordially invited to attend

MARSHALL N. FULTON, M.D., Secretary

WORCESTER NORTH DISTRICT
MEDICAL SOCIETY

The annual meeting of the Worcester North District Medical Society will be held at the Burbank Hospital Fitchburg on Wednesday April 22 1938. The oration will be delivered by Dr. Clifford L. Derick of Boston. His subject will be Staphylococcus Infection and Its Treatment.

Election of officers Dinner at 1 P.M.

GEORGE P. NORTON, M.D., President

FRANCIS M. MCMURRAY, M.D., Secretary

WORCESTER DISTRICT MEDICAL SOCIETY

Worcester Hahnemann Hospital Wednesday April 8 1938

PROGRAM

6:15 P.M. Dinner (Complimentary by Hahnemann Hospital.)

7:30 P.M. Business Session and Scientific Papers

1. Frontal Bone Osteomyelitis by C. A. Croissant, P. H. Cook and F. Wanson presented by Drs. Wanson and Cook
2. Undulant Fever—A Case Report with Necropsy by E. A. Fisher and J. Gottlieb presented by Dr. Gottlieb
3. Larostidin Treatment for Peptic Ulcer by J. A. Koraywo, D. G. Ljungberg, A. P. Lachance, L. P. Leland and A. D. Vamvas, presented by Dr. Koraywo

NOTICE

The next meeting of the Board of Censors for the Worcester District of the Massachusetts Medical Society will be held in the rooms of the Worcester District Medical Library 34 Elm Street, Worcester at four-thirty on the afternoon of Thursday May 7 1938. Application must be filed with the District Secretary two weeks before the time of the Censors Examination.

WILLIAM F. LYNCH, M.D., President

ERWIN C. MILLER, M.D., Secretary

SOCIETY MEETINGS
CONGRESSES AND CONFERENCESCALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY APRIL 6 1938

Monday April 6—

4:30 P.M. Boston Hospital Council, Lower Amphitheatre of the Out Patient Department of the Massachusetts General Hospital.

Tuesday April 7—

9-10 A.M. Boston Dispensary 25 Bennet Street Boston. Discusses and Injuries to the Hip Joint. Dr. John D. Adams.

2:30 P.M. Pediatric Ward Visit, Massachusetts Eye and Ear Infirmary.

8:15 P.M. Greater Boston Medical Society Auditorium Beth Israel Hospital.

Wednesday April 8—

9-10 A.M. Boston Dispensary 25 Bennet Street Boston. Recognition of the Early Psychoses Their Differentiation from Neuroses (Continued) Dr. A. Warren Stearns.

11:2 P.M. Clinico Pathological Conference Children's Hospital.

Thursday April 9—

8:30-9:30 A.M. Clinic, Surgical Staff of the Peter Bent Brigham Hospital at the Peter Bent Brigham Hospital.

9-10 A.M. Boston Dispensary 25 Bennet Street Boston. Development of Method in Psychopathology Professor Elton Mayo.

3:30 P.M. Medical Clinic at the Peter Bent Brigham Hospital.

Friday April 10—

9-10 A.M. Boston Dispensary 25 Bennet Street Boston. Rheumatism Fever Dr. Clifford L. Derick.

11 A.M. Massachusetts General Hospital. Clinical Meeting of the Staff of the Children's Medical Service, Ether Dome.

8 P.M. William Harvey Society Auditorium Beth Israel Hospital.

Saturday April 11—

9-10 A.M. Boston Dispensary 25 Bennet Street Boston. Hospital Case Presentation Dr. S. J. Thurnhauser.

10-12. Staff rounds at the Peter Bent Brigham Hospital.

Open to the medical profession

Open to Fellows of the Massachusetts Medical Society

BOOK REVIEWS

**National Medical Monographs. The Management of
Colitis J Arnold Bargaen 234 pp New York
National Medical Book Company, Inc \$3 00**

In his recent book, Bargaen has given an excellent picture of certain disturbances of the colon, including so-called mucous colitis, and ulcerative colitis. The latter is discussed in great detail and is covered in an excellent manner so far as the pathology, the x-ray findings, and the proctoscopic findings are concerned. So far as the etiology of the disease is concerned there is no doubt in the author's mind that he has found the cause of the disease when it is not due to tuberculosis, b dysenteriae, or amebiasis. Unfortunately, the majority of other investigators do not accept Bargaen's dictum as to the etiology of what is elsewhere called idiopathic ulcerative colitis, and it seems rather unfortunate that the matter should be treated in such a dogmatic manner as admitting of little or no doubt.

There is a welcome change in Bargaen's attitude as far as the results of treatment are concerned,—whereas, in previous years cure of the disease was the expected outcome of therapy, in this volume he says definitely "one should not speak of its cure but its control. This, of course, fits in better with the

experience of other men who realize the fundamental chronicity of the disease with a tendency to exacerbations and remissions

It also seems as if too little has been said as to the value of ileostomy in carefully selected cases, not from the point of view of curing the disease but as a life saving measure or as a means of placing a patient in the position of better economic security

Amebic dysentery is well described except for the fact that practically no mention is made of the fever which may accompany it in rather obscure cases due to its complication, liver abscess. Tuberculosis of the colon is well described. The discussion of mucous colitis is an excellent one from the point of view of description of the disease and treatment and could be read with profit by any practitioner

There is one fundamental mistake which appears in the book which the reviewer believes should be particularly noted. In one of the several illustrations, attention is called to the common reference of pain from various points in the large bowel. In his illustration, as well as in the text, it is noted that colonic pain is referred to a region high in the epigastrium in the midline, not far below the tip of the xiphoid. This is so far from being the case that it represents a very important diagnostic error inasmuch as colonic pain is almost always referred to a point well below the umbilicus

With the exception of the above criticism, the reviewer considers the book a valuable source of reference for the description of some of the major ailments of the colon

**Diseases of the Skin Frank Crozer Knowles Third
Edition 640 pp Philadelphia Lea & Febiger
\$6 50**

Dr Knowles' third edition has been thoroughly revised, with numerous new photographs. The field of general dermatology is well covered. Syphilis and the acute eruptive fevers are also considered. Numerous prescriptions and tables of diagnostic features are given and much that is new in therapy has been added

**Studies from the Rockefeller Institute for Medical
Research Reprints Volume 94 603 pp New York
The Rockefeller Institute for Medical Research.**

This group of reprints from the Rockefeller Institute covers a wide range of material from the various departments and from the hospital. Of special interest to clinicians are the various articles by Page and his associates on the relation of the renal nerves to hypertension. A group of papers from the Department of Plant Pathology cover various phases of the tobacco mosaic disease. One feature of special interest from the Department of the Laboratories is the report by Carrel and Lindberg on the culture of whole organs. This is an interesting and conservatively written report, giving in detail the procedures on which some press publicity developed last summer

NUMBER 15

THE DEVELOPMENT OF NEUTRALIZING SUBSTANCE FOR POLIOMYELITIS VIRUS IN VACCINATED AND UNVACCINATED INDIVIDUALS*

BY W LLOYD AYCOCK, M.D.† AND C C HUDSON, M.D.‡

THE observation made early in the study of poliomyelitis that one attack confers a lasting immunity suggested the possibility of artificial immunization. Many attempts have been made to protect against the infection particularly by the use of virus subjected to procedures designed to attenuate it. Aycock and Kagan¹ conducted a series of experiments with preparations of virus treated in various ways and failed to obtain either a highly efficacious or relatively safe method of immunization in fact the attenuated preparations proved but little if any safer than active virus. Since the method of attenuation seemed to have little bearing on the outcome, it was concluded that the result of injections of supposedly attenuated virus might have been determined rather by the particular tissue into which active virus was inoculated. The authors therefore attempted to immunize animals by such means as placing the virus in collodion sacs in the peritoneal cavity by intranasal instillation and by intracutaneous injection.

Through a long series of intracutaneous injections, it was possible to produce neutralizing substance uniformly, and the animals so vaccinated in the majority of instances resisted intracerebral inoculation of active virus eleven of twelve monkeys became immune. It is not clear whether the animal which succumbed (the second injected) developed the disease from intracutaneous injection or whether the virus was inadvertently introduced under the skin.

An additional thirty five monkeys were subjected to shorter series of intracutaneous inoculations, receiving in all 340 injections of virus. Neutralizing substance was produced in only about half of the animals half of this number later succumbed to intranasal instillation of active virus.

A further series of fifty four animals were injected subcutaneously with from 1 to 50 cc of

fully active virus or with virus preparations which had been subjected to attenuating procedures but which in all cases contained living virus. Each animal received from one to nineteen separate injections, 483 injections being given altogether. Only eleven of the fifty four animals succumbed to subcutaneous injections of material containing active virus. Some monkeys withstood as much as 30 cc of fully active virus, but failed to develop neutralizing substance succumbing either to intranasal instillation or intracerebral inoculation. Neutralization tests were done on sixteen of the surviving animals only nine neutralized the virus. Four of the ten monkeys later subjected to intranasal instillation of virus succumbed, six were able to withstand repeated intranasal instillation. Twenty five animals were later inoculated intracerebrally thirteen succumbing.

It appears from these experiments that the subcutaneous injection of active poliomyelitis virus, while relatively safe, is less effective in producing neutralizing substance or resistance to infection than intracutaneous injection. Furthermore it would seem that the artificial production of neutralizing antibodies in the blood serum of the experimental animal does not necessarily confer immunity to infection. However no firm conclusion can be drawn from these results concerning natural exposure, because it is not known how nearly intranasal instillation of virus approaches natural infection in regard to such factors as virulence and dosage.

DEVELOPMENT OF NEUTRALIZING SUBSTANCE IN THE HUMAN BEING FOLLOWING VACCINATION

During the summer of 1935 poliomyelitis was prevalent in a number of states on the eastern seaboard. An unusual increase in the number of cases in North Carolina in May marked the beginning of what was, for this southern state, an unusually severe outbreak. It reached its greatest intensity in the east central part of the state.² The outbreak attracted wide attention because the incidence is generally lower in southern than in northern states, and also because the seasonal increase was considerably in advance of that characteristic of northern states.

In the face of this unusual prevalence, vac-

*This work was financed by the Harvard Infantile Paralysis Commission and the Rockefeller Foundation.

†Aycock, W. Lloyd—Director of Research, Harvard Infantile Paralysis Commission, 1100 Hudson, C. C.—Health Officer, City of Greensboro, North Carolina. For records and addresses of authors see "This Week's Issue," page 74.

†No attempt was made to use blind mice because since it was found that larger amounts so injected did not produce the disease nor did they produce immunity with regularity.

ination, which has been recommended as a preventive measure against poliomyelitis, was used to a varying extent in a number of localities in North Carolina. Early in July, under the direction of the U S Public Health Service, a plan was formulated for administering the vaccine in such a way as to shed some light on its efficacy³. In Greensboro, somewhat to the west of the area of greatest prevalence, a group of about 300 children were chosen arbitrarily for vaccination and an equal number who applied were reserved as controls.

It was realized that statistically significant conclusions could be drawn from a comparative study of the occurrence of poliomyelitis in vaccinated and unvaccinated children only in the event that this particular city should be visited by an outbreak of a severe order, and of course this was questionable*. The authors felt that a study by means of the neutralization test on those vaccinated would afford evidence of the worth of the vaccine. The situation was particularly advantageous because tests could also be done at the same time on an equal number of individuals of the same ages who had not been vaccinated. From experience with the neutralization test, there are reasons for believing that an efficacious vaccine should produce neutralizing power in the blood serum.

In the experimental animal, infection with poliomyelitis virus results in immunity which can be detected by the neutralization test. This immunity is likewise present in human convalescents, as well as in a considerable proportion of individuals not known to have passed through an attack of the disease. From the distribution of this immunity in the population in general, the inference is that it results from exposure to the virus.

The parallelism of the results of the neutralization test to the incidence of poliomyelitis at different ages and in different populations makes it appear that the presence of neutralizing substance may be taken as an indication of immunity to infection with the virus. However, it is not known whether this neutralizing property in the blood in itself affords the protection, or is merely an accompaniment of what has come to be designated as "tissue immunity". That the presence of this neutralizing substance may not actually constitute protection is suggested by the fact that the experimental production of neutralizing substance does not necessarily confer resistance to intracerebral inoculation or even intranasal instillation of virus.

The procedure was carried out as follows. Blood was drawn from those to be vaccinated, usually just previous to the injection of the vaccine, and at the same time from a corresponding number of control individuals. Second bloods were taken from both groups from thirty-

one to seventy-seven days later (average sixty-one days), forty-eight being taken on the seventy-seventh day after the first bleeding.

The test was performed according to the method which has given fairly consistent results. A 5 per cent suspension of the spinal cord of a monkey sacrificed in the height of experimental poliomyelitis was mixed with an equal amount of the serum to be tested. The mixture was kept at 37°C for two hours, and overnight in the icebox. Usually six to ten sera were set up in each experiment. As controls, normal monkey serum and convalescent serum were included in each experiment.

In three of the thirty experiments done, none of the animals succumbed. All these were done with a single specimen of virus. These experiments are not included in the results, since the indications are that this particular sample of virus was not active. In all the other experiments, roughly one-half of the monkeys succumbed. In four instances, normal monkey sera apparently neutralized the virus, but when the test was repeated they failed to do so. This discrepancy is in keeping with our previous experience, where such a divergent result has been obtained on an average one out of six times. However, since this error is reversible, it is believed that readings on any considerable number of tests are dependable. In the whole series of experiments, only once did the convalescent serum fail to neutralize the virus, however, this serum did neutralize in a number of repetitions.

It may be objected that the technic used in the neutralization test was not sufficiently delicate to detect degrees of immunity which would protect against infection, but which would not neutralize the virus. It may be said that the test was not so severe but that approximately half the children neutralized the virus in the beginning, a figure which is in keeping with epidemiologic expectations for those of similar age. Furthermore, it would be expected that if the vaccine increased the titer of immunity, some who did not respond to the test in the beginning would do so after vaccination.

First and second bloods from the same children were usually included in the individual experiments, as well as sera from both vaccinated and controls. The results of paired tests on sixty-three children are shown in table 1.

Single tests were also done on sera from thirteen vaccinated individuals and nineteen controls whose immunity status was not expected to change. Experience has shown that if the sera of the first bleeding neutralized the virus it could be assumed that the second would do likewise, and that if the second blood tested initially, did not show neutralizing property, neither would the first. These single tests and the assumptions made on the other of the pair are shown in table 2.

*No cases of poliomyelitis occurred among the vaccinated children nor did any occur among those in the group who were not vaccinated.

Attention should be called to the fact that the increase in immunity shown on table 1 cannot be interpreted as being of the order indicated, since there are included only those indi-

viduals on whom both tests were done. In other words this tabulation considers those who became immune during the period of the experiment, but disregards a considerable number whose status obviously did not change. Table 3 summarizes the results of all the tests.

A indicates that the result was assumed that if the first blood neutralized the virus the second would do likewise if the second blood did not neutralize neither would the first.

* B. Brodie vaccine, & Kolmer vaccine.

It will be noted that there was an increase in immunity in both groups under observation—19.5 per cent in the vaccinated and 14.9 per cent in the controls (table 3). In view of the irregularities of the neutralization test and the small number of observations, it is not clear that the slightly greater advantage of the vaccinated over the controls was the result of vac

cination The immunity increase may have been due, at least largely, to natural exposure. The occurrence of eight cases of poliomyelitis in the city during the period of the experiment is evidence that the virus was prevalent there at the time. Other factors, too, are concerned in the evaluation of the vaccines. In the first place, about half of those who were vaccinated were already immune according to the neutralization test, and so presumably would not be benefited. Secondly, a change from non-immune to immune occurred in about 24 per cent of those vaccinated and 17 per cent of the controls, an advantage of only about 7 per cent for the vaccinated group. This figure is very small, even assuming that the production of neutralizing substance affords protection. As a matter of fact, the experimental production of immunizing substance does not always constitute adequate protection against infection. In any case, the results of this work indicate that the value of vaccination against poliomyelitis as carried out in Greensboro was slight.

Certain other tests were done, sometimes on the first blood and sometimes on the second, where contamination of the other of the pair precluded comparative readings. These are not included in the report, but it may be said that the addition of these tests would not alter significantly the percentage of positive or negative findings in any of the groups.

Perhaps there would have been less confusion if the blood sera had been paired beforehand and equal numbers of tests done on vaccinated and control individuals. It was thought best, however, to conduct the series of neutralization tests on the sera as unknown. To this end, the identity of the samples was withheld until the outcome of the test had been recorded. Later, in order to insure the inclusion of a sufficient number of paired sera (that is, first and second bleedings from the same individual), this information was furnished, although the status of the individual, whether vaccinated or control, was not revealed until the result had been recorded.

The outcome of these tests affords an opportunity for emphasizing the danger of attempting to draw conclusions from small series of neutralization tests. The results obtained by another observer of tests performed on six children in Greensboro, before and after vaccination, were submitted to us for comparison. Before vaccination, five out of six failed to neutralize the virus. Four individuals neutralized the virus after vaccination. Thus, it might be concluded from this small experiment that the vaccine was highly efficacious in producing neutralizing substance.

On table 1, which records the results of our

neutralization tests, the sera are arranged according to the numbers given when the blood was taken. Let us consider Nos 84 to 93. These individuals possessed the same immunity status as did those in the primary tests done by the observer referred to above, that is, five failed to neutralize the virus before vaccination. Four of these were immune after vaccination. Again, if we refer to the controls on table 1, we shall find six consecutive specimens, Nos 53 to 62, five of which failed to neutralize on the first test, three of these were immune on the later test. Thus, it will be seen that in dealing with a test of this sort, where on the average the results in the beginning are positive or negative in about 50 per cent, a reasonable number of tests must be done in order to show significant changes from this figure.

SUMMARY AND CONCLUSIONS

Tests to determine whether neutralizing substance was produced by two poliomyelitis vaccines in use in North Carolina were done on the blood of twenty-eight individuals before and after vaccination. It was found that 46.4 per cent were already immune. After vaccination, 75 per cent neutralized the virus, an increase of 28.6 per cent.

Neutralization tests on thirty-five control individuals showed 40 per cent immune on the first bleeding and 62.8 per cent on the later bleeding, an increase of 22.8 per cent.

It thus appears that there was a considerable increase in immunity in both vaccinated and control individuals. However, the actual increase in immunity is not so high as the figures indicate, for the reason that the tabulation does not include a number of individuals, both vaccinated and controls, in whom it was apparent from one test that there could be no change in immunity status. When these tests are included, the increase in immunity is 19.3 per cent in the vaccinated individuals and 14.9 per cent in the control individuals.

It is a question whether the somewhat greater increase in immunity in the vaccinated group is significant. Since an increase occurred in both vaccinated and control groups, it seems reasonable to infer that it was due, in large part at least, to natural exposure. The occurrence of eight cases of poliomyelitis in the city during the period of the experiment bears witness to the prevalence of the virus.

A NOTE ON THE COMMON OCCURRENCE OF SERIOUS INVOLVEMENT OF THE HEART IN HYPERPIESIA

BY PAUL D. WHITE, M.D.*

IT is well known that essential hypertension (hyperpiesia) is compatible with seemingly good or excellent health in the first few years of its existence in the majority of patients and that it is in that period often an accidental discovery. It is also well known that if persistent and more than slight it usually leads, with or without other complications such as coronary disease, to enlargement of the heart and eventually to heart failure. As a cause of world wide heart disease it looms high. Unfortunately by the time hypertensive heart disease itself becomes evident the condition has advanced to a stage where little but palliation is possible. Heart failure may be checked or relieved for a few years but the fundamental factor—the hyperpiesia—is out of control, in the present state of our knowledge, despite the temporary effect of various more or less radical and nonspecific therapeutic measures.

Recently I have had occasion to make a survey of the cases of hypertension that I have seen in my practice as cardiac consultant. Certain interesting and somewhat unexpected findings and the depressing results of a follow up study have caused me to present this brief note.

In fifteen years among 5,808 patients (3,396 or fifty eight per cent males and 2,412 or forty two per cent females) with symptoms or signs suggesting the possibility of cardiac abnormalities there were 1,249 cases with hypertension (twenty two per cent).† Almost every case was of the type of essential hypertension or hyperpiesia. Only forty nine were thought to have an important degree of nephritis and only a few of those gave indications that the nephritis was primary rather than secondary. Only two cases were recognized as having congenital coarctation of the aorta. Almost every case had had hypertension for at least a few years before consulting me, a common duration of known hypertension was five to ten years, in a few cases the known duration was but a few weeks or months or as long as twenty or twenty five years.

Cardiac enlargement was discoverable with out great difficulty in the majority of the cases, and it was doubtless present even if not discernible clinically in many others, a few cases might be styled potential hypertensive heart disease but there were doubtless far fewer of these in my practice than in that of the average family doctor or insurance examiner or spe-

cialist in hypertension itself. It is probably the difference in the types of practice that explains some of the other findings which may be in contrast to those of general practice.

Among the 1249 hypertensive cases there were 644 males (fifty-one per cent) and 605 females (forty nine per cent) (making up nineteen per cent of the total of 3,396 males in the entire series of patients and twenty five per cent of the total of 2,412 females), in contrast to the reputed great preponderance of females with uncomplicated hyperpiesia.

Satisfactory analysis of the community at large has not yet been made, however with reference to the sex incidence of early or uncomplicated hyperpiesia. Certain selected groups have been reported in which the female incidence has been found greater than the male, for example in the Outpatient Department of the Boston City Hospital where women made up 76.1 per cent and men 23.9 per cent of 1,787 cases (corrected for sex incidence in total cases to 74.3 per cent and 25.7 per cent respectively).¹

My cases belonged preponderantly in the older age groups—thirty three under forty years, 126 between forty and fifty, 386 between fifty and sixty, 467 between sixty and seventy, and 237 over seventy, thus the great majority (sixty eight per cent) were between fifty and seventy. Males and females were almost evenly distributed in the age groups.

Angina pectoris was present in 329 of the cases (twenty six per cent) when they first consulted me. A fact of great interest concerning the relationship of hypertension and angina pectoris in the total series of 5,808 patients is that there were almost as many females as males with both conditions, 147 women compared with 182 men out of the total of 329 cases, in contrast to the great preponderance of men over women (782 compared with 247) of the 1,029 cases of angina pectoris in the entire group. Thus only 182 of 782 males with angina pectoris had hypertension while there were 147 hypertensive cases among the 247 females with angina pectoris.

Coronary thrombosis had occurred in recognizable form in ninety nine cases (eight per cent) and came later in others. Congestive heart failure was the chief cause for the consultation in 308 cases (twenty five per cent) and was a later complication in many more. It frequently took the form of pulmonary congestion, often acute as in cardiac asthma, in fact pulmonary congestion with dyspnea was the first evidence of failure in nearly every case except when the whole heart quickly failed or some

*White, Paul D.—Assistant Professor of Medicine, Harvard University Medical School. For record and address of author see "This Week Issue," page 74.

†If we exclude the unimportant cases of certain functional disorders the percent becomes twenty seven (of the so-called "organic" cases).

complication like mitral stenosis was also present to cause earlier failure of the right ventricle with resulting dropsy. Coronary thrombosis sometimes seemed to be the exciting factor for the congestive heart failure in this series of hypertensive cases.

Rheumatic heart disease was definite in forty-three of the cases, with mitral stenosis in twenty-three of them. Cardiovascular lues was clearly present in only ten patients and thyrotoxicosis in six. Aortic regurgitation without evident stenosis was present in fifty-two cases, while aortic stenosis was present in thirty-three and was frequently of high degree—a surprising finding. At least two cases had dissecting aortic aneurysms, as proved by autopsy.

Auricular fibrillation was present in 170 of the cases, being paroxysmal in fifty-five. Fifty-eight patients complained of paroxysmal tachycardia with regular rhythm. Many cases had premature beats. The great majority of the patients were electrocardiographed, thirty-four showed auriculoventricular block and forty-three intraventricular block, most of the cases showed left axis deviation with or without inversion of the T waves in Lead I.

Neurocirculatory asthenia was present in easily recognized degree in 137 of the 1249 cases, diabetes in eighteen, and gout in seven. Seventy-four of the patients had had apoplexy and a number more developed this complication later.

The causes of death were determined in 100 consecutive cases (sixty-five male, thirty-five female). Ninety-five died "cardiovascular-renal" deaths: fifty-three from congestive failure (including seven from acute pulmonary edema), twenty suddenly (known angina pectoris in five of these and Adams-Stokes attacks in another), eleven from acute coronary thrombosis, six from apoplexy, and five from uremia. Five died as the result of infection, including three from pneumonia. The ages at death in this series of 100 cases were between thirty and forty years in two, between forty and fifty in five, between fifty and sixty in twenty-three, be-

tween sixty and seventy in forty-two, between seventy and eighty in twenty-six and over eighty in two.

Thus the great majority (seventy-two per cent) died before the age of seventy and of cardiovascular disease closely connected with the hypertension, few lived long lives.

It is true that our ignorance of the fundamental causes of hyperpiesia and of their cure does not allow us as yet to prevent the condition or to control it even at its inception, but it is also quite clear that the earliest weeks or months of the disease present the most favorable time for a study of its causative factors and for attempts to retard its progress. To discover the onset of hyperpiesia in any patient, to study it then, and to begin whatever sedative or other therapy seems effective should be, it seems to me, one of the aims of the practitioner of medicine whether he be engaged in family practice or in routine institutional or life insurance medical work as Palmer² and others have suggested. To accomplish this aim nothing short of annual examinations of all adults is possible. This will doubtless come to pass some day.

There has been a tendency in the postwar period to swing too far from the old extreme of great and general fear of high blood pressure to the other extreme of reassurance and relative neglect because we wish to avoid making our patients neurotic and particularly since we are still ignorant of the cause and the cure of hyperpiesia. We should, however, face the facts and take the middle course.

In conclusion, then, as the result of a discouraging experience with chronic and advanced hypertensive heart disease, I would urge the early discovery of hyperpiesia in patients and more intensive study and attempts at treatment at its onset.

THE RADIOLOGICAL MANAGEMENT OF CANCER OF THE BREAST*

BY RICHARD DRESSER, M.D.,† AND VALMORE A. PELLETIER, M.D.‡

THE radiological management of cancer of the breast is not a standardized procedure. Much controversy still exists as to the indications for roentgen and radium treatment and

the dosages employed. It is the purpose of this article to set forth as concisely as possible the radiation methods now in use in several of the cancer clinics in Massachusetts. This is done with the full appreciation that some of these methods are at variance with those of other workers.

The treatment of early localized cancer of the breast is primarily a surgical problem. When the disease is confined to the breast and there are no axillary or distant metastases, five year

*Material for this publication has been collected from the Pondville Hospital at Norfolk (Massachusetts State Cancer Hospital), the Collis P. Huntington Memorial Hospital, Harvard University, and the Memorial Hospital, Worcester, Massachusetts.

†Dresser, Richard—Roentgenologist, Collis P. Huntington Memorial Hospital and Pondville Hospital at Norfolk. Pelletier, Valmore A.—Surgeon to Out Patients, Pondville Hospital, Wrentham. For records and addresses of authors see *This Week's Issue*, page 742.

cures should follow radical mastectomy in 50 per cent to 70 per cent of the cases. When the axillary glands are involved, this figure is reduced to about 25 per cent. The best radiological treatment can scarcely hope to improve or even equal these results. Unfortunately all cases are not amenable to surgery.

In a series of 600 cases collected from several representative cancer clinics, 38.5 per cent were considered suitable for radical mastectomy, 31 per cent were inoperable and 30.3 per cent showed recurrence after operation elsewhere. Most of the inoperable and recurrent cases (more than 60 per cent of the entire group) were treated radiologically and the roentgenologist was called upon for help in many of the more favorable cases.

One may conveniently establish four groups: (1), primary operable cases, (2) cases inoperable because of the extent of the disease locally, the presence of distant metastases, or the unfavorable general condition of the patient, (3), cases presenting local recurrence or metastases following surgical removal of the breast, (4) cancer of the breast in young women.

GROUP I PRIMARY OPERABLE CASES

The clinical criteria of operability are well known. The mass should be movable on the chest wall, the skin should not be extensively involved. A carcinoma which has eroded the skin and broken down may still be operable when as if there is a diffuse lymphatic invasion of the skin the so-called inflammatory type surgery is contraindicated. Moderate involvement of the lower axillary glands does not contraindicate operation but reduces greatly the chance of cure. Enlargement of glands above the clavicle contraindicates surgery.

The differentiation of benign and malignant tumors of the breast by means of soft tissue radiography as recommended by Warren has in our experience, proved of little value. In a series of 100 cases in which radiographs of the breast were made we were usually able to confirm a positive clinical diagnosis of cancer but in those cases which were clinically doubtful the roentgenograph was often misleading. In several instances sharply defined nodules which were interpreted as benign proved on histological examination to be malignant.

One of the most important contraindications to surgery is the presence of visceral or bony metastases. Even though the local growth seems operable these secondary deposits may be present and give no symptoms. Metastases in the lungs and bones can usually, but not invariably, be demonstrated by roentgen examination.

The results in a series of 500 cases of cancer of the breast examined roentgenologically with

a view to determining the incidence of pulmonary and osseous metastases will be briefly discussed. A more detailed report of this study will be presented in a subsequent communication. Of the 500 cases examined, 293 showed no metastases, seventy-three showed metastases to the lungs only, eighty-six had metastases in the bones only, and forty-eight showed metastases to both bones and lungs. (Table I.) The

TABLE I
CARCINOMA OF BREAST

Total Cases Examined	500 — 100.0%
No Metastases	293 — 58.6%
Metastases to Bones or Lungs	207 — 41.4%
Metastases to Lungs Only	73 — 14.6%
Metastases to Bones Only	86 — 17.2%
Metastases to Both Bones and Lungs	48 — 9.6%

distribution of bone metastases in order of frequency is shown in table 2.

TABLE 2
CARCINOMA OF BREAST

Total Cases Showing Bone Metastases	134 — 100%
Pelvis	86 — 64%
Spine	84 — 62%
Lumbar Spine	68 — 50%
Dorsal Spine	51 — 40%
Cervical Spine	23 — 17%
Skull	60 — 44%
Extremities	57 — 42%
Shoulder Girdles	42 — 31%
Ribs and Sternum	40 — 31%

It will be noted that metastases in the bones occur with slightly greater frequency than metastases in the lungs. It is therefore fully as important to examine the skeleton preoperatively as it is the lungs. This immediately raises the question of expense. In only one case in the entire series was a metastasis discovered in an extremity without concomitant involvement of the skull, spine, pelvis or lungs. It is therefore not essential to include the long bones in the routine examination of the skeleton. This makes a very appreciable reduction in the cost. It is now our practice to take the following films preoperatively: a lateral view of the skull (8 x 10 film), a lateral view of the dorsal spine (14 x 17 film), an anteroposterior view of the lumbar spine and pelvis including the upper ends of the femora (14 x 17 film), a postero-anterior view of the chest (14 x 17 film). If this preoperative roentgen examination is carried out routinely a number of useless mastectomies will be avoided and the surgeon will be spared the discomfort of having patients return a few months or even weeks after operation with symptoms from metastases which were in reality present before operation.

If it is concluded that the local growth is operable and that there are no distant metastases

the question of preoperative radiation arises. There are many advocates of this procedure, foremost among them the Radiumhemmet in Stockholm. In our opinion there are several disadvantages to preoperative radiation which outweigh the possible benefits: first, many cancers of the breast are not particularly radiosensitive and the delay of several weeks which preoperative radiation entails should be avoided, secondly, to obtain regression of a cancer of the breast the radiation dosage must be sufficiently large to produce a severe erythema of the skin. This frequently causes some delay in healing of the wound postoperatively. More important, however, is the danger of late radio-dermatitis. We have seen a number of cases of carcinoma of the skin which developed many years after the original cancer of the breast had been cured. There is also some danger of damage to the lungs which results in pulmonary fibrosis. When radiation offers the patient the only hope of cure or greatly enhances the possibility of cure, one is justified in chancing the development of late untoward radiation reactions. Surgery will eradicate the disease *locally* in about 80 per cent of the operable group. Most of those who die succumb to glandular, visceral, or bony metastases. Thus it seems unwise to subject this entire group to the hazard of radiation damage when benefit will accrue to hardly more than twenty per cent. It is our opinion that preoperative radiation should not be practised routinely, but should be limited to a small group of borderline cases in which there is some doubt as to the possibility of completely eradicating the disease by surgery.

Next to be considered is postoperative radiation. The danger of late untoward radiation reactions applies here as it does with preoperative radiation. We have discontinued routine postoperative treatment, but there are, however, certain cases in which it is indicated: first, when there has been a simple amputation of the breast without dissection of the axilla, secondly, when there is gross or microscopic disease in the axillary nodes, thirdly, women who have not passed the menopause. This last group will be discussed under a special heading.

A word should be said regarding the radium treatment of operable cancer of the breast. This is carried out by implanting long platinum needles of low radium content (2 or 3 milligrams) or "gold wires" containing radon (radium emanation). The implants are usually left in place for about a week giving a dose of from 10,000 to 20,000 milligram hours. This method is available in only a few clinics which possess the necessary apparatus. Although encouraging results have been reported by several workers, it is our belief that this procedure should not be recommended as a substitute for surgery in favorable cases.

GROUP II INOPERABLE CASES

About 60 per cent of the cases of carcinoma of the breast presenting themselves at a cancer clinic are unsuitable for surgery. Radiation is the best method available at present for the treatment of these unfortunates. If the disease has not progressed beyond the axillary and supraclavicular glands and the patient is in good general condition intensive radiation to these areas is indicated. Proper treatment will frequently result in regression of the disease and marked palliation. If distant metastases have developed, the case may be considered hopeless and one is scarcely justified in intensive radiation of the local lesion. High-voltage roentgen rays produced by at least 200 kilovolts peak with a filter of at least one-half millimeter copper are employed. The breast is irradiated by the "cross-fire" method with the patient lying on the affected side. The rays are directed from below upward through a large field covering the lateral aspect of the breast and axilla. When this area has been given the desired dosage the rays are directed from an overhead tube to the medial aspect of the affected breast with the patient still lying on the affected side. A third field including the supraclavicular area is frequently employed. With this technique excessive dosage to the lung is avoided since it is irradiated only through the lateral portal. The roentgen (r) unit which is based on the amount of ionization produced by the rays in one cubic centimeter of air is accepted as the standard of dosage. All measurements reported in this article are made without back-scattering of rays from the patient. Seven hundred r will produce a mild skin erythema when given through a fifteen by fifteen centimeter portal in one sitting. Treatments are given in daily doses of 300 r to 400 r. A total of 1500 r to 1600 r is delivered to the lateral portal and a similar dose to the medial portal. The entire treatment is completed in eight to ten days. About a week after the completion of the series, a stiff erythema with some blistering develops which may cause the patient much discomfort for several days. This reaction will always clear up and the patient should be assured of this fact. Following the treatment to the breast it is often advisable to irradiate the supraclavicular region giving a total of 1600 r to 1800 r in daily doses of 300 r to 400 r. Occasionally the local lesion is treated by the implantation of radium needles as described under Group I, and sometimes by a combination of radium and roentgen rays. One may expect regression of the disease in a large percentage of cases which are intensively irradiated. Following this intensive radiation subsequent treatment must be given with great caution, since the normal tissues never recover completely from this dosage.

When the disease recurs in an area which has been heavily irradiated it sometimes progresses

with great rapidity. This is particularly true of the inflammatory type of cancer. These extensive recurrences are sometimes mistaken for a radiodermatitis.

The direct effect of radiation on distant metastases is usually disappointing. Occasionally deposits in the parenchyma of the lung may regress with dosages of about 1200 r to the front and back of the chest, and the accumulation of fluid resulting from involvement of the pleura may sometimes be retarded. Metastases to the abdominal viscera, particularly the liver are refractory and it is useless to radiate them. Bone metastases show little response to direct radiation but in young women may regress secondarily following cessation of ovarian function. This will be discussed more fully under Group IV. Irradiation may have a marked analgesic effect, particularly in those cases with involvement of the spine. Complete relief from pain is often secured by moderate dosages even though there is no demonstrable regression of the metastatic process. As little as 600 r to 800 r delivered over the spine may serve to make the patient comfortable for a period of months.

GROUP III POSTOPERATIVE RECURRENCES

The percentage of local recurrences following radical mastectomy should be small provided the cases have been properly chosen for operation. These recurrences may appear as small superficial nodules in the skin, many of which may be easily palpated although they are not visible. Such lesions often do exceedingly well with roentgen ray dosages of 1500 r to 1800 r given in a period of a week or ten days. The larger, more indurated areas of local recurrence with involvement of the chest wall are less responsive but many of these lesions may also be controlled.

Postoperative axillary and supraclavicular recurrences are treated in much the same manner as described under Group II. When extension to the remaining breast occurs the technique of radiation is essentially the same as that employed in an inoperable case. In exceptional instances surgical removal of the second breast may be indicated.

The treatment of remote metastases has been discussed under the previous heading.

GROUP IV CANCER OF THE BREAST IN YOUNG WOMEN

Cancer of the breast in young women is generally more malignant than in those who have passed the menopause, and ends fatally in a large percentage of cases.

Leo has tabulated the results of 191 cases of cancer of the breast in women under forty which

were treated by radical mastectomy. At the end of three years only 15 per cent were alive and free of disease. A smaller series of forty-eight cases collected by one of us showed only 12.5 per cent free of disease three years after amputation of the breast. It is well known that a cancer of the breast may progress with unusual rapidity during pregnancy. There is much experimental evidence to show that some relationship exists between ovarian function and certain cases of breast cancer. Surgical removal of the ovaries was practiced in Germany as early as 1889 (Schmizinger) and in England in 1896 (Beaton). Palliative results were obtained in about one third of the cases of cancer of the breast in young women subjected to oophorectomy. Castration can be more easily and safely carried out by high voltage roentgen radiation than by surgery. A dose of 600 r to the front and back of the pelvis respectively using a 15 x 15 centimeter portal at a distance of 50 centimeters will produce within two months a cessation of menstruation in the average sized woman thirty five or older. The dose in the region of the ovaries must be increased in younger women. This can best be accomplished by extending the focal skin distance from 50 to 80 centimeters.

The results of ovarian radiation in fifty-nine cases of cancer of the breast with bone metastases have been reported in detail in another article. Thirty of these cases were women who had not reached the menopause and twenty-nine had passed the menopause. In 30 per cent of the premenopausal group there was definite regression of the bone metastases following roentgen castration. These patients were relieved of symptoms for periods varying from several months to three years. In the postmenopausal group there was not a single instance in which bone regeneration following ovarian radiation could be demonstrated.

The results of ovarian radiation in the advanced cases of cancer of the breast in young women have led us to extend the method to a more favorable group. When the growth is locally operable, a radical mastectomy is performed. About ten days after the operation intensive postoperative roentgen treatment is given to the operative site. This consists of a series of daily treatments of 300 r to 400 r until a total of 1600 r to 1800 r has been reached. Radiation is then directed to the pelvis as above described. We are not prepared to draw definite conclusions from this group, but the results have thus far been encouraging. It is our hope that this regimen may at least serve to delay local and metastatic recurrences in about one third of the cases. The danger of future pregnancy is eliminated which alone justifies the procedure.

DUODENAL STUMP CLOSURE IN GASTRIC RESECTIONS WITH A MODIFIED FURNISS CLAMP

BY HOWARD M. CLUTE, M.D.*

ALL surgeons who do resections of the stomach recognize both the importance of adequate duodenal closure and the difficulties which this maneuver may entail. No part of a gastric resection is more likely to be followed by fatal complications if improperly done than the closure of the duodenal stump. The writer has found that a modification of the Furniss clamp for intestinal anastomosis has been very successful in expediting and simplifying this stage of gastric resection, and wishes to report its use in several cases. It is felt that, with this modification of the Furniss clamp, a fairly standard technique of approach to duodenal closure can be established.

About a year ago an attempt was made by the writer to close the duodenal stump during a subtotal gastrectomy by placing the Furniss clamp on the duodenum and then folding over the cauterized surfaces while they were held by the Furniss pin. The procedure was accomplished with difficulty because the hinge of the clamp is at the distal end and because it was impossible to put the holding pin or needle in from the distal end (Fig 1).

FIG 1 Plate from manufacturer's advertising, showing Furniss clamp. Note hinge at distal end. Pin can be inserted only from proximal end of clamp.

A modification of the Furniss clamp was therefore, worked out with the cooperation of Mr. George Hiller of Hiller & Hensen, Boston.

FIG 2 Author's modification of Furniss clamp. Hinge at proximal end of clamp. Pin can be inserted from either end of clamp. Less crushing pressure is obtained with turnbuckle at center.

Mass primarily for use in closing the duodenal stump in gastric resections. As will be noted in fig 2, the hinge of the clamp is at the proximal

*Clute Howard M.—Professor of Surgery, Boston University School of Medicine. For record and address of author see This Week's Issue, page 74.

end and a screw and turnbuckle for tightening the pressure is in the center of the clamp. The pin to hold the edges of the shrunken gut together may be inserted from either the proximal or distal end of the clamp. This point is most important since in closing the duodenum a needle with catgut swedged on may be inserted from the distal end of the clamp through the entire width of the gut. This is impossible in the original Furniss clamp.

The writer has now used this modified Furniss clamp in three cases of subtotal gastric resection with excellent results. In fig 3 the particular

FIG 3 Method of closing duodenum with modified clamp using straight intestinal needle instead of pin to hold duodenum after division from stomach. Tying the suture closes the stump without soiling, and inversion can then be carefully done.

steps in the technique are shown. The stomach and duodenum are prepared for resection by ligation of the major blood supply along the greater and lesser curvatures. The modified Furniss clamp is applied in such a way that the edge of the duodenum as it is crushed comes just to the distal end of the clamp. In place of the usual Furniss pin a straight intestinal needle is inserted through the distal end of the clamp to hold the duodenum (Fig 3a). An occlusive Ochsner clamp is placed proximally on the stomach.

The duodenum is now divided with the actual cautery and the modified Furniss clamp removed. This leaves the duodenal stump held tightly shut by the intestinal needle (fig 3b).

which can then be drawn through so that its attached suture puckers the shirred end as it is tied (fig 3c). The duodenal stump is now still further occluded by either continuous or interrupted mattress sutures (fig 3d). Adjacent fat is caught in with a third layer of mattress sutures and the duodenal closure is complete. Once the duodenum has been sufficiently freed to receive the clamp its division and closure require but a few minutes.

The writer wishes to express his indebtedness to Dr. Furniss for the inherent advantages of this clamp and for the idea of using a threaded needle to close the end of the intestine. The change in Dr. Furniss's clamp which has been made in no way alters its fundamental principles but does, in the writer's opinion, make them more readily applicable in certain situations, such as duodenal stump closure.

RECRUDESCENCE OF OVARIAN FUNCTION AFTER HEAVY IRRADIATION*

Two Cases

By GEORGE VAN S. SMITH, M.D.†

RADIUM applied inside the uterine cavity in doses under 1000 milligram hours practically never induces a permanent amenorrhea in women under the age of thirty-five. This statement is based on limited experience both at this clinic and elsewhere in the treatment of patients with excessive and/or prolonged uterine bleeding or fibroids. The amount of irradiation necessary to bring about a permanent amenorrhea in these cases or in women with normal ovarian function is not established although one would assume that at least 1200 milligram hours and probably 1600 to 2400 milligram hours would suffice. The size and position of the uterus and ovaries, the distance of the ovaries from the source of irradiation and the amount of filtration would have to be taken into consideration.

In the majority of women over the age of thirty-five intrauterine application of 1200 milligram hours is generally accepted as adequate to produce a permanent menopause providing there is no tangible structural abnormality of the internal genitalia and the filtration does not exceed the equivalent of one millimeter of platinum. This dose might not be sufficient in cases of fibroids since the tumors may displace the ovaries far enough away from the radium so that in reality they receive a comparatively small exposure. Nor would it be sufficient presumably in cases of ovarian tumors mistaken for fibroids since enough functioning ovarian tissue might lie beyond the range of the radium. Furthermore, exception should be made in cases of granulosa cell tumor, in which the cells are so active in secreting the female sex hormone that 1200 milligram hours of radium might not inhibit them even though the tumor was so small as to be impalpable and the ovaries were not displaced. At this clinic one such in-

stance in which radium failed to inhibit the bleeding associated with a granulosa cell tumor has been encountered.

The patient, Miss A. L. M., a private case of Dr. F. A. Pemberton, aged fifty-three was seen in July 1925 because of profuse bleeding four years after the oophorectomy. Biopsy revealed endometrial hyperplasia with polyp formation. At that time granulosa cell tumor was not suspected. The uterus was only moderately enlarged and no other pelvic abnormality was palpable. She was treated by the intrauterine application of radium (two 50-milligram glass capsules, screened by one-half millimeter of silver and one-half millimeter of brass for 24 hours)—2400 milligram hours. Seven years and three months later the patient returned because of almost constant flowing with hemorrhages at times. Complete hysterectomy was performed. The uterus was moderately enlarged. Marked endometrial hyperplasia bordering on malignancy, diffuse hyperplastic adenomyosis of the uterine wall and a four millimeter granulosa cell tumor (thecal cell type) at the median pole of the right ovary which was not displaced, were found. Convalescence was uneventful and the patient remains well two and one-half years after operation. At the present time irradiation would not be employed in cases showing hyperplasia of the endometrium some time after a well-established menopause since this finding constitutes an almost infallible criterion of the presence of granulosa cell tumor the accepted treatment of which is operation.

The report of the following two cases is prompted first because they experienced periodic uterine bleeding after truly large doses of radium secondly because functioning endometriism was obtained thus indicating a return of ovarian activity and thirdly because a survey of the literature indicates that no similar instances have been recorded.

CASE 1. Mrs. C. B., aged thirty-eight was admitted on August 30, 1920 because of daily flowing for six weeks. She had had no pain and had been perfectly well until the present illness. She had had six children and three abortions. On examination the cervix was slightly lacerated and felt a little hard. No other pelvic abnormality was discerned. Biopsy revealed early but highly malignant squamous carcinoma in the endocervix and radium was applied. Two 50-milligram glass capsules screened by one-half millimeter of silver and one

* From the Free Hospital for Women, Brookline, Mass.

† Smith, George Van S.—Assistant Visiting Physician, Lathrop Medical Clinic, Director of Research, Free Hospital for Women, Brookline, Mass. For record of history of a thoracic "Tubercle" see page 74.

millimeter of red rubber, were placed in tandem in the cervical and uterine canals and four 25 milligram glass capsules, screened by one-half millimeter of silver and set around the periphery of a one-half millimeter brass pill box, were abutted against the cervix and vaginal vaults—200 milligrams in all—and were allowed to remain for thirty hours, giving a total dosage of 6000 milligram hours. The vagina was packed with gauze to hold the radium in place and to keep bladder and rectum away.

For six months following irradiation there was no flowing and only slight watery discharge. The patient then experienced what she considered regular and normal monthly periods. There were no hot flushes, she felt well and was gaining weight. In January, 1930, she had menorrhagia of three weeks' duration, followed by a return of normal cycles. During 1931 there was occasional slight intermenstrual staining. On examination in January, 1932, no palpable or visible evidence of pelvic disease could be found. She was again examined in April, 1932, because of menorrhagia of two weeks' duration and some scarring was felt in the broad ligaments. In May, 1932, she was examined under anesthesia. There was slight erosion of the cervix and biopsy showed only chronic inflammation. The fundus was enlarged to twice normal size, it lay in the second degree of retroversion and was freely movable. No adnexal abnormalities were palpable. The cervical canal was easily dilated and found to be smooth. The distance from the external os to the top of the uterine cavity was three and one-half inches. No polyps or irregularities were made out and the curettings showed the picture illustrated in figure 1. On rectal examination soft scarring was

FIG 1 Path no 20347 Photomicrograph of endometrium ($\times 80$) removed five years and eight months after the local application of radium 200 milligrams for 30 hours. It shows late proliferation and some dysplasia.

felt in the broad ligaments. Because of the menorrhagia and the endometrial activity the condition was considered dysfunctional and radium was the elected treatment, first, because the patient was well in all other respects, secondly, because the tissues had reacted so well previously to irradiation and thirdly, because excessive obesity seemed to be a contraindication to operation. Two 50-milligram capsules covered with one-half millimeter of silver

and placed in tandem in a one-millimeter brass tube were inserted into the uterine cavity and allowed to remain for sixteen hours—1600 milligram hours in all. Convalescence was satisfactory. When last examined, in January, 1936, nine years and four months from the time of her first admission, the patient was well and had had no flowing or discharge. No evidence of disease could be seen or felt.

CASE 2 Mrs B L O, aged twenty seven, entered the hospital in March, 1927. She had come to the outpatient department because of prolonged flowing following her previous menstruation and was referred to the house at once because of a suspicious lesion of the cervix. She had had six pregnancies. A rush biopsy during anesthesia showed only chronic cervicitis, but the celloidin section later disclosed early carcinoma. Radium was employed—50 milligrams, screened by one-half millimeter of silver and one-half millimeter of brass, were inserted into the cervical canal and 175 milligrams, screened by one-half millimeter of silver, were distributed about the periphery of a pill box of one-half millimeter of brass, which was placed against the cervix and fornices—225 milligrams in all—and allowed to remain for twenty-four hours, giving a total dose of 5400 milligram hours. Convalescence was uneventful and an artificial menopause ensued. In August, 1928, the patient was examined under anesthesia because of occasional staining after intercourse. The upper third of the vagina was closed by adhesions, which were broken, the stenosed cervix was dilated. Biopsies showed only the reaction from irradiation. There was diffuse scarring across the pelvis, which was considered due to irradiation.

Again in September, 1931, the patient was examined under anesthesia. There was less induration across the pelvis, but the vaginal adhesions and cervical stenosis had recurred. The adhesions were broken and the cervix dilated. No evidence of cancer could be found, the curettings consisted of atrophied endometrium and necrotic tissue.

In 1933 the patient had what she considered regular and normal periods for six months. From January until August, 1934, she had had three periods. At this time she was again examined under anesthesia. No cancer could be detected, the uterine cavity was two inches deep and curettage disclosed a functioning endometrium, as shown in figure 2. Her latest follow-up was in December, 1935, eight years and eight months from the time of irradiation. She was well except for a rare hot flush when tired. Menstruation had been regular and normal since the fall of 1934.

Discussion One's first thought is that these cases may have had ectopic ovarian tissue or a granulosa cell tumor. These possibilities cannot be ruled out in case 1, but seem unlikely, since the patient responded so well to the second treatment, remaining symptom free thus far for three years and eight months. The diffuse enlargement of her uterus at the time of the second treatment, on the other hand, is a finding suggestive of the presence of a granulosa cell tumor. If case 2 had ectopic ovarian tissue, a return of function would have been expected sooner. The fact that her menstruation has been normal since reestablishment is on the whole against the presence of a granulosa cell tumor, although one case with normal menstruation, normal endometrium and a granulosa

coll tumor has been encountered at this time. The finding of an endometrium showing the corpus luteum effect does not bear any weight for or against granulosa cell tumor, since secretory endometrium has been found in patients with these tumors when no other source of progesterin could be demonstrated.

It could be argued that, since all the radium was not placed in the uterine cavity the ovaries

Furthermore the distance between the lateral fornices and normally located ovaries may not be more than one and one half centimeters greater than that between the uterine cavity and the ovaries and may even be less to the outer poles than that from the uterine cavity.

It has been commonly accepted that ovaries are endowed at birth with their full quota of primordial follicles. The hormone studies of recent years have cast doubt on this concept and suggest that follicles may be developed from the ovarian stroma in extrauterine life. The fact that case 2 had a secretory endometrium (indicating the presence of a corpus luteum and hence previous ovulation) after so long a period of amenorrhea may be interpreted as evidence for the evolution of a new crop of primordial follicles. It does not seem at all likely that any follicles which might have survived irradiation would have remained inactive for so long a time. Since only one biopsy of the endometrium from case 1 was made and did not show any corpus luteum effect, no deductions can be drawn as to whether follicles may have developed *de novo*.

SUMMARY

Two cases are reported which experienced cyclic uterine bleeding following massive doses of radium and from which biopsies revealed functioning endometrium thus indicating a recrudescence of ovarian activity. The finding in case 2 of an endometrium showing the corpus luteum effect is taken as presumptive evidence for the development *de novo* of ovarian follicles after a long period of quiescence.

FIG. Path. no. 22216 Photomicrograph of endometrium (X 50) removed seven years and four months after the local application of radium, 215 milligrams for 14 hours. It shows the midsecretory phase and some dysplasia.

really may not have received much of the massive dose. In this connection it can only be stated that thus far, none of nine similar cases similarly treated and surviving for the same periods have had a return of cyclic bleeding.

BENJAMIN SHATTUCK OF TEMPLETON— MEDICAL PRACTITIONER*

BY GEORGE CHEEVER SHATTUCK, M.D.†

ANCESTRY

BENJAMIN SHATTUCK the subject of this paper was of the fifth generation of Shattucks in this country. He belonged to the Littleton branch of the family, was born on November 11, 1742 in Littleton (Middlesex County) Massachusetts, but moved to Templeton (Worcester County), Massachusetts and died there on January 14, 1794.

Besides the Shattucks of Littleton other branches of the family were already established in Deerfield, Cambridge, Andover, Pepparell

Groton and Holms in Massachusetts and there were still others in New Hampshire and in Connecticut.

The name of Shattuck has since become widely diffused in the United States but it is possible that the lineage of all persons in America now bearing the name of Shattuck might be traced to a common ancestor namely to William Shattuck who was born in England in 1621 or 1622. There is no doubt at any rate that our Benjamin was descended directly from this William Shattuck, who arrived in Boston as a boy without parents or resources. As early as 1642 William Shattuck's name was recorded as owner of a small grant of land in Watertown. Probably most of his time was de-

*Read at a meeting of the Boston Medical History Club at the Boston Medical Library, December 16, 1935.

†Shattuck, George Cheever—Assistant Professor of Tropical Medicine, Harvard University Medical School. For word and address of author see "This Week's News" page 74.

voted to farming but he bequeathed a loom to his son William

William the younger (1653-1732) continued to live in the homestead in Watertown where he followed farming, brick-making and other employments such as were usual in the frontier life of those days. This William had a son, the Reverend Benjamin (1687-1763), who was graduated from Harvard College in 1709 studied theology there and, subsequently was ordained the first minister of Littleton. The Reverend Benjamin had eleven children, of whom Stephen was the eldest. Stephen (1710-1801) became a farmer in Littleton and, at the age of sixty-five, took part in the Concord fight on the 19th of April, 1775, and followed the enemy to Cambridge.

Our Benjamin Shattuck, the second son of Stephen, became the first physician in his direct line of descent which, in the four succeeding generations, counts five physicians*. Among Benjamin's forbears and close relatives of the name of Shattuck, there had already been three other physicians*. They belonged respectively to the second, third, and fourth generations.

BACKGROUND

Although the massacre of the people of Deerfield by the Indians in 1703 could only have been remembered by old people at the time when Benjamin was born, there was, even in his youth, a line of forts in the southern part of New Hampshire. One of these built by Capt Daniel Shattuck (1692-1760), was called "Shattuck's Fort"†. It was near the Connecticut River in Hinsdale and it consisted of two houses built on either side of a brook. They were enclosed in a strong palisade of timbers and thick planks surmounted by pickets. In the upper part were posts for sentinels and holes to fire through. During the Indian Wars in 1745, and subsequently, the whole people of the neighborhood came to this fort to live. When the men of Hinsdale labored in their fields or went to church, they had then guns with them, and there were always sentinels on guard. In 1746 the Indians fired upon four men near Shattuck's Fort, but hurt none and, in 1747, they set fire to the fort at night and part of it was destroyed.

Although Benjamin's family and then neighbors had nothing to fear from Indians, the French and Indian Wars did not terminate until 1763 and while Benjamin was growing up, stories of Indian fighting must have been narrated at the Shattuck fireside by actual participants.

As a boy Benjamin doubtless made himself generally useful on his father's farm. He must have turned his hand to many things for, in

those days, families living in the country produced the food they ate and raised the flax and wool which were to become linen and homespun, or knitted socks and undergarments for winter wear. The candle-mold was part of the necessary equipment and the warming-pan was in common use until a much later day. Travel was by stage-coach or on horseback. Boston thirty miles away as the crow flies, could not be visited easily.

I imagine that the school at Littleton in those days was extremely elementary and that it absorbed little of the time or energy of the pupils. Benjamin was fortunate, however, in having been fitted to enter Harvard College by Jeremiah D. Rogers, son of the clergyman of Littleton.

An old pamphlet entitled "A Memoir of Dr Shattuck", which is both anonymous and undated, bears internal evidence of having been written some years after the death of Benjamin. It seems quite possible that the author may have been Benjamin's son, Dr. George Cheyne Shattuck the elder. Extracts from this quaint document read as follows:

"While at Cambridge Shattuck was considered a young man of good capacity, a hard student, with an original cast of thought which sometimes appeared like eccentricity.

"It was then a period remarkable for boldness of thinking, and freedom in the expression of liberal opinions on great national questions.

The spirit of liberty has always been first invoked in the groves of learning. The sacred flame which was soon to burn through the land and warm every breast was frequently seen at that time to flash and enlighten in the halls of Harvard. Among those whose observations are remembered by those few who were students at that time and are still living Dr Shattuck held a distinguished rank. In questions of philosophy as well as of government he was one of the pioneers in liberal discussion."

The freedom of thought and boldness of expression which existed in Harvard College in these early days indicate the political temper which led to revolution and denotes a falling away from the Calvinistic concepts of the Puritan settlers.

Benjamin Shattuck was graduated from Harvard with the Class of 1765, which, although it numbered only 54 members, was considerably larger than any of the earlier classes.

MEDICAL CAREER

After graduating from College, Benjamin went to Groton where he became apprenticed to Dr. Oliver Prescott, an outstanding physician and patriot. Prescott, also a graduate of Harvard College, had been trained in medicine by the apprentice system but, many years later, he received an honorary M.D. from Harvard.

*Appendix I

†Captain Daniel Shattuck of the Hinsdale branch of the family was a distant cousin of Benjamin. See *Memorials of the Descendants of William Shattuck* by Lemuel Shattuck, 1855 Boston: Dutton and Wentworth.

Dr Prescott had a large practice in the surrounding country where he made his professional calls on horseback. Thacher* says of Dr Prescott that he had learned to sleep in the saddle when returning home from a distance at night, and that this facility enabled him to do a tremendous amount of work.

Dr Frederick C Shattuck used to say that one of Benjamin's duties as apprentice was to take care of Dr Prescott's horse. Doubtless the apprentice did other chores as well but he must have received from Dr Prescott as good a medical training as was commonly attainable in the American Colonies in those days. Thus apprenticeship probably lasted four or five years for the 'Mémorial' mentioned above indicates that Benjamin began practice in Templeton in the year 1770 and it says specifically that he settled there by invitation of the townspeople.

If one attempts to picture the physician one should know something of the setting in which he lived and worked. Like many other New England towns Templeton was built upon a hill and in those early years, most of the houses may have been of logs. With reference to conditions of medical practice in those days the 'Mémorial' says:

The practitioner of the present day with all the lights of the last half century about him can hardly understand how much his predecessors suffered for want of books, instruments, and all the facilities which are at the command of the modern physician and surgeon.

The place Dr Shattuck chose for the field of his exertions was a new settlement with but few inhabitants at that time. The population increased but slowly in the new corporations until after the Peace of 1763. Then Indian warfare was no longer to be dreaded and the hardships of the colonies made rapid strides in cultivating the soil. Dr Shattuck thought and his visions were more than realized that by the time his children had grown up there would be a comparatively dense population around him. With these hopes his professional duties began.

The life of a physician who has business and with it entertains a high sense of his responsibility is always an arduous one but few can imagine the severity of his labours who maintains a considerable celebrity in a new and thinly settled country.

In Thacher's account of Dr Israel Atherton (1740-1822)† there are passages which give further insight into the status of the physicians of that time. Dr Atherton graduated from Harvard College in 1762 and began practice in Lancaster three years later. He had received

his medical training under Dr Edward A. Holloke of Salem. Thacher says that, in most country towns preparatory knowledge was deemed of little value except for the pulpit or the bar, and that the practice of physic was only in name among the learned professions. When Atherton began practice he was the only physician in the County of Worcester who had passed a course of collegiate studies, or commenced the profession of medicine under the advantages of a competent preparation. For a long period he was the only physician in the county to become a Fellow of the Massachusetts Medical Society. He lived however (says Thacher) to witness what he ardently strove to promote: an emulation among the faculty to elevate their profession to a respectable standing in science and substantial usefulness, and to see the patronage and preference which the community had so generally extended to in posters in a great measure withdrawn.—Hon O Fiske.

A word should be said at this point about hospitals and medical schools of the period. The history of these makes it highly improbable that any hospital was accessible to Benjamin Shattuck or to his patients.

The development of American medicine has been vividly portrayed by Mumford* and more fully described by Packard†. In the first half of the 18th Century large general hospitals were unknown and no academic medical instruction was being given in the Colonies.

In 1761 Dr Thomas Bond launched his plan for a great municipal hospital for Philadelphia. Of earlier hospitals Mumford says (page 91) that 'It must not be supposed that nothing in the nature of provision for the afflicted had ever been established before in the colonies. From the commercial character of the country, as Beckwith says, it may readily be supposed that our first medical establishments were lazarettos or hospitals intended for the reception of seamen and others infected with contagious disorders. Such institutions existed in the Delaware and in Boston Harbor and numerous small private institutions were established in different parts of the country to facilitate the practice of inoculation for smallpox as that treatment came generally to prevail. But those were not hospitals in the all embracing sense. They were small, very limited in their means and scope, and, in the lazarettos especially, the medical attendance was of the most meagre sort and the care of patients inefficient and often abominable.

Fortunately for Philadelphia Benjamin Franklin who had long been interested in medicine took a hand in the campaign to raise funds

* New York M.D. 1814. American Medical Biography

Philadelphia p. 96.

* New York M.D. 1842. "A History of Medicine in America" Philadelphia & London
Philadelphia p. 1. April 1921. "History of Medicine in the United States" Vol. 1 New York.

for the proposed hospital in Philadelphia. Probably, he knew more about certain aspects of medicine than did many a practising physician of the time. In the words of Mumford (page 82)

"He recognized the futility of asking for subscriptions for so novel a project before a popular demand had been created, so he proceeded to create the demand. As he says, 'Previous, however, to the solicitation I endeavored to prepare the minds of the people by writing in the newspapers on the subject, which was my usual custom in such cases, but which Dr. Bond had omitted'."

In the following year, 1752, a house was rented and made ready for patients. Such was the humble beginning of the Pennsylvania Hospital, the precursor of all our great general hospitals. The second great hospital, that of New York, was granted its charter in 1770 (Mumford page 101). It was not equipped and started, however, until 20 years later (1791)*, and the Massachusetts General Hospital did not admit its first patient until 1821 when our Benjamin had been for many years in his grave.

Academic medical training began in Philadelphia in 1765 when Morgan and Shippen were appointed respectively to the chairs of the "Theory and Practice of Medicine" and of "Anatomy and Surgery". Three years later, Kuhn became Professor of "Materia Medica and Botany" and, in the year following, the great Benjamin Rush began his lectures as "Professor of Chemistry". It was during these years that Benjamin Shattuck was getting his medical training in Gtoton. Dr. Prescott must have known of the new School in Philadelphia but he may have hesitated to recommend it to his pupil until its worth had been proved by time. Probably, too, the pupil could not have afforded a visit to Philadelphia.

Be that as it may, in subsequent years Benjamin Shattuck studied the writings of Cullen of Edinburgh and of other leaders of medical thought in Great Britain. Apparently, he admired particularly the works of George Cheyne of London and Bath, for he named a son George Cheyne Shattuck. This son succeeded his father as a physician and became a leading practitioner and medical teacher in Boston.

Two years after beginning his medical practice, Benjamin Shattuck married Lucy Barron† of Chelmsford. They had seven children, of whom Dr. George Cheyne Shattuck the elder was the fifth.

When Benjamin Shattuck went to Templeton, the nearest sizable town was Worcester, which was about twenty-five miles distant in a direct

line, whereas Boston was fifty-five miles away and it was forty-three miles to Springfield.

Worcester* had been settled in 1685, wiped out by the Indians in 1701, and resettled in 1715. By 1790, while Benjamin was still in active practice, the town of Worcester had 2095 inhabitants. Much Indian corn and rye were raised in Worcester County, but not much wheat, because rye did better there. The natural forest growth consisted largely of oak, walnut, chestnut, and pine. In or near the town were grist mills, sawmills, fulling-mills and trip hammers.

Moreover, from Worcester as the center, "West India goods" were supplied to the surrounding country, for Worcester was on the great post-road from Boston to Springfield, and various other roads converged there.

I imagine that Benjamin Shattuck occasionally went to Worcester on horseback to see a patient or to make a purchase. His medical equipment must have been carried in saddle-bags. In them he may have had a variety of potent purgatives and emetics, some surgical instruments and a lancet for blood-letting. Certainly, he did not have a stethoscope, for Laennec did not publish this great discovery until 1819. Neither could Benjamin have had a clinical thermometer for the "Medical Reports" of James Currie of Liverpool, describing the use of thermometers in medicine, did not appear until 1798†, four years after Benjamin's death. Moreover, the clinical thermometer did not come into general use until after Wunderlich's treatise appeared in 1868‡.

Unless my memory plays me false, Dr. Frederick C. Shattuck told me years ago that the clinical thermometer was first used at the Massachusetts General Hospital by Benjamin Shattuck's grandson, George Cheyne Shattuck the younger. The thermometer which he used was shaped like a fish-hook. The short arm was placed in the axilla and the temperature was read on the longer, projecting arm.

Quoting again from the old "Memoir" "For twenty-four years Dr. Shattuck continued his labours in the County of Worcester and the neighboring Counties until his strength sank under his efforts." "He died of a pulmonary complaint in the year 1794. His mind continued bright and active until the last moments of his life. He reasoned and judged upon his own case with the calmness of one not interested in the event, and named to his medical friends with prescient accuracy the number of hours the mortal machine would, by the common course of Nature, continue its functions."

"Those who lived with him and were the best judges of his talents and acquirements

uniformly agree that no physician of that time was more acute in discovering the seat and causes of a disease than Dr Shattuck. To quick discernment was added a patience of investigation of all the circumstances relating to the subject under consideration which naturally led to correct views and happy results.

"His knowledge was considerable but his wisdom was superior to his knowledge. He knew much of the thoughts of other men but was governed by a system formed from his own. He bailed with delight the works of Cul len and other distinguished lights in his profession, but received their opinions as intellectual food, for digestion, rather than absolute guides of his own practice. He was systematic in his course of examining, reasoning, judging, and acting but was not, like many wedded to systems." "He was often consulted by his professional bretheren in stubborn cases and his judgment was considered by

them as the '*ultima ratio medicæ*' " "There were several physicians highly respectable in their day and generation, who were on most friendly terms with him, and years after he was gone, bore testimony to the soundness of his judgment and the success of his practice. Drs. Foxcroft, Atherton and Frink were among the number, all men of distinction in their profession."

At Benjamin Shattuck's funeral, a eulogy was delivered by the Reverend Ebenezer Sparhawk and on the death of Benjamin's wife in 1821 (then Mrs. Rice) a sermon was preached by the Reverend Charles Wellington. The eulogy and the sermon were printed for private distribution and were bound together at the request of George Cheyne Shattuck the elder but little can be found in them about the life of Benjamin or that of his wife.

Such is the simple story of Benjamin Shattuck of Templeton medical practitioner

DOES MODIFIED MEASLES CONFER LASTING IMMUNITY?

BY JAMES H. TOWNSEND, M.D.*

SINCE the adoption of various methods for modifying measles by the use of immune blood, convalescent serum, or placental extract, the question has been raised whether the disease, so attenuated, would confer an immunity of long duration. If it were shown that an appreciable number of persons having the modified disease later developed it again within a few years, this would constitute a valid objection to the widespread use of this treatment.

With this question in mind a follow-up was made of a group of individuals who experienced modified measles approximately ten years ago.

In a boarding school epidemic of sixty-five cases of measles in February 1926 thirty-two individuals received 9 cc. of convalescent whole blood at least eight days before the development of the rash and experienced distinctly milder symptoms than their confreres who were not so treated. The differences in maximum temperature, duration of febrile period, occurrence of complications, and character of rash were described at that time.¹

Replies have recently been received from all thirty-two of these individuals who were con-

sidered to have had modified measles ten years ago. In no case have any of them experienced a subsequent attack of measles. Nine individuals indicated in their replies that they had, to their knowledge, come into intimate contact with the disease, some of them several times. Five others stated that they had been present in communities while measles epidemics had been in progress, but did not know of direct contact. The others made no observations about possible exposures, but most of them were in school or college for about six out of the ten years, and probably had ample opportunity for exposure.

Conclusion. Replies from thirty-two individuals who had modified measles ten years ago indicate that none of them have experienced a subsequent attack of measles although many of them are known to have been amply exposed. There is no evidence to date that the active immunity conferred by modified measles is any less satisfactory than that conferred by the unmodified disease.

ERADICATION OF TUBERCULOSIS

With improved measures of control which are within the limits of practicability, including better detection and isolation of open cases, with higher standards of living and personal hygiene, there appears to be no fundamental reason why tuberculosis may not be virtually eradicated from large areas in this country. While there are certain contingencies which obviously might bring about a recrudescence after the disease has reached an extremely low level, it does not appear that this result is inevitable in accordance with any accepted biological law or that it is especially to be anticipated.

Admitting that we cannot actually know the future of tuberculosis, it is none the less important that we should clearly define what are reasonable expectations in the light of present knowledge, since present activities in study and control necessarily are directed chiefly toward the future. If, as I believe it is reasonable to anticipate control to the point of permanent regional suppression, the establishment of this as the objective has obvious and important implications as to the scope and intensity of control measures. It has less obvious but important implications with respect to indicated lines of

investigation.—*Excerpt from an address by Wade H. Frost, Am. Rev. of Tuberc., December, 1935*

DO YOU KNOW?

DEMENTIA PRAECOX

Each year from 15,000 to 20,000 individuals fall victims to what is known as dementia praecox soon after adolescence or in the first flush of manhood or womanhood. Properly handled about 40 per cent of these can be returned to effectual life, but the other 60 per cent will go on to a disorganization of personality that will be associated sooner or later with the intellectual deterioration that will make it necessary to segregate them.

Announcement has just been made that a fund of \$40,000 has been made available for a program of investigation and study of dementia praecox under the guidance of leaders of American psychiatry. The National Committee for Mental Hygiene states that the money has been given by the Ancient Accepted Scottish Rite, Northern Masonic Jurisdiction.—*Bulletin, Public Relations Bureau, New York State Medical Society*

CASE 22151

PRESENTATION OF CASE

A forty-five year old white American salesman entered complaining of pain in the right leg.

The patient had been perfectly well until about fifteen hours before entry, at which time while writing at his desk he was suddenly seized with a terrific pain in the upper portion of his chest both anteriorly and posteriorly. The pain moved downward through the epigastrium and finally remained constant in the lower mid abdomen. Almost immediately afterward both legs became numb and cold. The skin became blue and the slightest movement caused severe pain. He was removed at once to a hospital. About five hours after the onset the left leg became perceptibly warmer but the right remained unchanged. Two hours later he was catheterized. Examination of the urine sediment was negative. The pain in the abdomen and the entire right lower extremity remained unabated despite the administration of morphine. Eleven hours after the onset the right leg was definitely colder and more cyanotic than at the previous examination. No pulsations were palpated in the femoral artery or any of its branches. Pulsation of the arteries in the left leg was present but weaker than normal. He was transferred to this hospital shortly afterward.

Physical examination showed a well-developed and moderately obese man unable to walk and complaining of pain in the right lower extremity. The fundi showed slight nicking of the vessels. The heart was moderately enlarged to the left. The sounds were strong, regular and there were no murmurs or thrills. The blood pressure was 190/110. The lungs were negative. The right lower abdomen was found to be slightly cooler than the left. The left leg was warm, normal in color and showed a moderately strong dorsalis pedis pulsation. There was no palpable arterial pulsation in the right leg and the limb was anesthetic to the hip. Its surface was cool but not cold. The toes were bluish and color was regained ten seconds after applied pressure was removed. The leg blanched rapidly upon

elevation. Movement of the hip was extremely painful. Oscillometric studies showed no pulsation in the right leg. On the left side the oscillation was three points stronger than in the arm.

A catheterized specimen of urine showed total hematuria.

X-ray examination showed slight elevation of the left diaphragm. The aorta was quite tortuous but not dilated.

Directly after admission by a transperitoneal route a three inch thrombus was removed from the right common iliac artery. No bleeding occurred from the proximal segment of the vessel. Eight hours postoperatively the right leg was unchanged in appearance. The blood pressure was 130/60. Excretion of urine was quite scanty and the patient was catheterized. The urine continued to be bloody. A few râles were heard at the lung bases but the heart findings were unchanged. Three hours later the patient became anuric. Cyanosis and dyspnea ensued and the chest became filled with bubbling râles. He went rapidly downhill and died thirty-six hours after the onset of his illness.

DIFFERENTIAL DIAGNOSIS

DR. SOMA WEISS* This is then an unusual and dramatic story of a middle-aged man who after enjoying good health is seized by pain and in whom thereafter within thirty-six hours preceding his death disturbances in several parts of the body follow in rapid succession. These disturbances at first seem somewhat bizarre and unrelated.

1. A "terrific pain" was felt in the upper portion of his chest anteriorly and posteriorly which soon moved down through the epigastrium into the lower mid abdomen where it remained persistent.

2. Both legs became numb and cold. He was unable to walk. The skin became blue and as I understand it the movements of both legs caused severe pain.

3. The ischemic state of the left leg gradually improved in the course of hours so that eleven hours later fair, though weaker than normal pulsations are observed. Oscillometric reading also revealed fair pulsations. The skin was of normal color.

4. As these improvements occurred in the circulation of the left leg, the ischemic state of the right leg progressed and no pulsation was obtained over the femoral and other arteries below Ponsart's ligament. The limb became anesthetic up to the hip and movements of the right hip were extremely painful. Tests indicated nevertheless that the ischemia was not complete and gangrene was not present.

5. The right side of the lower portion of the abdomen became slightly cooler.

*Assistant Professor of Medicine, Harvard Medical School, Assistant Director of Thorndike Laboratory, Boston City Hospital.

6 In spite of the fact that the urine sediment was normal two hours after the onset of the seizure, about eleven hours after onset there developed a "total hematuria"

7 The heart was somewhat enlarged. The arterial pressure was elevated. The aortic shadow was tortuous.

We have no additional laboratory tests of aid.

(May I ask, if the question is permitted, what the temperature, the heart rate and serology were at entrance to the hospital? After all, even we of the City Hospital have such information.)

DR TRACY B MALLORY The pulse rate was 90, and the temperature 99° at entrance.

DR WEISS It is at this point of the clinical story that a clinical diagnosis had to be made. Let us try to make it. I must say I am somewhat embarrassed, for you have invited me to discuss the differential diagnosis of this case, and I cannot offer one. There is but one condition, as far as my interpretation goes, which is characterized by all manifestations presented by this patient, and that is *dissecting aneurysm* of the aorta. It would be far-fetched to suspect multiple embolism here. I realize on the other hand, that dissecting aneurysm is a rare condition, and instances of its correct diagnosis are even rare.

But, if a man in middle age or later as a result of hypertension and focal medial degeneration of the arch of the aorta develops a slit through the intima and media within the arch, he can have exactly the same type of pain as this patient has had. As the dissection proceeds downward toward the iliac artery, the pain will travel down into the lower abdomen, particularly if the intercostal and lumbar branches are compressed or torn off. If the dissection involves both iliac arteries, ischemia may result in both lower extremities. But why should the circulation improve in the left leg? The answer to this question is not clear, but one conjecture is that the dissection may have reruptured into the main arterial and hitherto compressed lumen. The coldness of the right lower abdomen suggests that in addition to the compression of the common iliac, compression or tearing off of right lumbar branches of the arteries was present. The total hematuria is a rather unusual feature of dissection-aneurysm. It must indicate dissection of at least one renal artery or compression of its orifice, and infarction of the kidney.

Is the fact that x-ray revealed a "tortuous but not dilated" aorta for or against dissecting aneurysm of the thoracic portion of the aorta? This, in my opinion, is neither for nor against, but entirely compatible with dissecting aneurysm. The x-ray picture of the dissecting aneurysm can vary from no change to fusiform dilatation of the descending aorta at times with

a darker central and a lighter peripheral shadow, or there may be wide shadows of one or more of the large branches of the aortic arch. All these changes depend on the width and on the direction of the dissection which can be narrow and partial or wide and complete with all transitions. The tortuous picture obtained in this case indicates either that the aorta was tortuous as a result of sclerosis and the associated section was narrow or that the tortuosity was caused by the irregularity of the dissection.

Let us now examine the sequence of events after admission. Do they confirm or contradict our diagnostic impression? The patient was operated upon apparently for a suspected embolus in the right iliac artery. This is entirely compatible with a mistaken diagnosis of a dissecting aneurysm. I know of two cases in which embolectomy was performed for suspected embolus in the brachial artery, imitated by the dissected and compressed artery. In a third case "acute abdomen" was suspected but no pathology was found on exploration. Postmortem examination revealed dissection of the abdominal aorta.

The fact that after removing three inches of thrombus no bleeding occurred from above, confirms the suspicion that the acute ischemia of the right leg was caused by the dissection of the iliac artery rather than by an embolus. The anuria that followed may well have resulted not only from dissection and compression of the renal arteries but also as a result of the added factor of shock.

Death was rather sudden, associated with cyanosis, dyspnea, and pulmonary edema. This is entirely compatible, though the evidence is inadequate to call it characteristic, with cardiac tamponade, by far the most common cause of death in dissecting aneurysm.

In conclusion, to me the simplest and most obvious interpretation of the sequence of events in this case is as follows:

- 1 Arterial hypertension. Cardiac hypertrophy.
- 2 Focal degeneration of the media of the arch of the aorta. Medionecrosis aortae cystica.
- 3 Intimal tear within the arch invading and dissecting the media, causing thoracic pain.
- 4 Dissections down to and involving the iliac arteries. Possible rerupture of the dissection into the left iliac artery. Dissection and compression of the right iliac artery. Circulatory ischemia of the right leg.
- 5 Dissection of the renal arteries with compression and possible infarction with resulting hematuria and anuria.
- 6 Possible compression or tearing of the lower intercostals and lumbar arteries (right) causing pain and coolness over the right side of the abdomen.
- 7 Probable hemopericardium and cardiac

tamponade from the dissection rupturing into the pericardium causing pulmonary edema, circulatory collapse and death.

Dr. MALLORY Dr. Holmes, can you add anything?

Dr. GEORGE W. HOLMES The diaphragm is obviously high on the left side. That is difficult to explain unless there was something directly below it pushing it up or possibly paralysis of the phrenic nerve. The heart is enlarged to the left and shows a characteristic picture of hypertrophy of the left ventricle. The supra-cardiac shadow is increased and the aorta looks actually wide in this film. Of course this is not a film taken at seven foot distance and there is a good deal of magnification but I think one would almost be justified in saying there was slight dilatation of the aorta. It may all be due to tortuosity. There is nothing in this film that would allow me to interpret a dissecting aneurysm but I would agree that there is not evidence against it.

CLINICAL DIAGNOSES

Embolus, right iliac artery
Ascending thrombosis of abdominal aorta
Hypertensive and coronary heart disease

Dr. SOMA WEISS'S DIAGNOSES

Dissecting aneurysm of the abdominal aorta and medionecrosis cystica, with the complications as listed above

ANATOMIC DIAGNOSES

Dissecting aneurysm of the thoracic and abdominal aorta and with partial dissection of the left renal and left common iliac arteries

Medionecrosis cystica.

Cardiac hypertrophy hypertensive type

Infarcts of the kidney

Pulmonary edema and congestion bilateral

Operative wound removal of thrombus of right iliac artery

Dr. MALLORY I think it is probably only fair to say that the history as Dr. Weiss had it was obtained at successive intervals and a good deal of it was not known at the time the patient was operated on. His diagnosis is entirely correct and is accurate down to many of the small details. There was a dissecting aneurysm. In most of the dissecting aneurysms that we have seen the rupture in the intima has been a relatively short distance above the aortic valve and the dissection has run over the arch and down the remainder of the aorta. In this case the rupture in the intima was just at the apex of the arch, and the ascending aorta was not involved. The dissection carried the entire length of the aorta and extended down into the left iliac artery for a distance of six

or seven centimeters where a rupture had again occurred in the intima and the stream of blood came back into the iliac artery, accounting in that way for the return of pulsation in the right leg. On the right side the dissection did not go so far. It stopped just before the bifurcation, and the aortic intima at this point was ballooned up to form a valve across the mouth of the right iliac artery completely occluding it. The thrombus which Dr. Smithwick found was the ordinary secondary thrombosis of stagnating blood beyond a point of vascular obstruction. The dissection had involved the left renal artery but not the right. The affected artery beyond the point of obstruction was thrombosed and multiple irregular small infarcts were found throughout that kidney. It is a little hard to understand why with obstruction of the main renal artery one should not get total infarction of the kidney, but only the cortical part and not all of that was infarcted. There must have been a fairly extensive collateral circulation. With the point of intimal rupture as high as it was in this case, actually in the arch with the ascending aorta uninvolved there was no chance for rupture into the pericardium. The exact mechanism of death was not apparent.

Dr. HOLMES Was the left kidney large?

Dr. MALLORY There was no difference in the two in gross.

Dr. HOLMES Any explanation for the high position of the diaphragm?

Dr. MALLORY No.

A PHYSICIAN What was the clinical discharge diagnosis?

Dr. MALLORY Embolus of the right iliac artery and thrombosis of the abdominal aorta.

Dr. WEISS Was there any involvement of the branches of the lumbar or intercostal arteries?

Dr. MALLORY Not so far as we could tell. In these cases, however, the layers of the aortic wall are sometimes separated several millimeters from each other. The various branches of the aorta, unless they are torn free from their intimal attachment, must traverse this space where they are subjected to external pressure from the surrounding blood which may be of a magnitude equal to or even greater than that within their lumina. In this way they are subject to compression which may or may not lead to obliteration and circulatory arrest. It would obviously be impossible from the anatomic findings to determine what the relative pressure relationships may have been during life.

Dr. WEISS What did histologic examination of the aorta itself show?

Dr. MALLORY The aorta in various places showed a definite though mild degree of medionecrosis cystica. It is a degree of the process that we find quite often in routine autopsies,

not so severe in fact as several that I have picked up in routine sections. Just why in this particular case rupture and dissection should have occurred is not clear. In the entire group of dissecting aneurysms that we have seen there was less abnormality of the aorta in this case than in any of the preceding ones.

A PHYSICIAN: Can it be said definitely that the phrenic arteries were not involved?

DR MALLORY: We did not specifically investigate them.

DR HOLMES: The dissection extended up to what we call the aortic knob?

DR MALLORY: Yes, it began at just about that point, I should say.

DR HAMPTON: Was it all around the aorta or just on one side?

DR MALLORY: It ran about two-thirds of the way around. They rarely are complete.

The correct diagnosis in this case was made by Dr. Thompson, the resident in cardiology, and various other people.

CASE 22152

PRESENTATION OF CASE

First Admission. A fifty-one year old white American dining car steward was admitted complaining of pain and swelling of the right fifth toe.

The patient, a known diabetic for two years, had sharp steady pain in his right fifth toe for about a week. This had begun as a small reddened area with subsequent swelling of the toe. Later the entire foot and ankle became swollen and tender and yellowish discharge exuded from the primary area.

The patient had been treated satisfactorily for his diabetes with insulin and diet for two years. A year before a lumbar puncture showed 192 cells per cubic millimeter, all of which were lymphocytes. A Wassermann test of the spinal fluid was positive. The total protein was 60 milligrams. An x-ray taken at that time showed no enlargement of the heart or any abnormality of the lung field.

Physical examination showed an elderly man lying flat in bed coughing occasionally. The skin and mucous membranes were pale. The left pupil was irregular but both pupils reacted to light. The heart was not enlarged. A coarse blowing systolic murmur was audible at the aortic area and was transmitted into the vessels of the neck. A_2 was clear and sharp. The blood pressure was 188/80. There was a slight increase of tactile fremitus and coarsening of the breath sounds at the right base, where a few coarse râles were audible. All the pedal arteries showed normal pulsation. A local area of necrosis with a foul-smelling discharge was observed upon the right foot. The entire foot was reddened, edematous, and tender. The reflexes were all normal.

The temperature was 102.5°, the pulse 100. The respirations were 20.

Examination of the urine was entirely negative. The blood showed a white cell count of 19,300.

On the day following admission the right fifth toe was amputated. His temperature continued to show daily rises to 100° or 101°. He continued in good condition for about a month and a half except for small sloughs arising in the region of his operative wound. At this time routine examination showed bile in his urine. He became rapidly jaundiced and had an icteric index of 25. Both the liver and spleen became palpable but he complained of no discomfort. The stools persistently contained bile. About ten days later the jaundice which had been slowly progressive, subsided slightly and a guillotine amputation of the right lower leg was done. The jaundice deepened thereafter and a liver function test showed 100 per cent retention. The icteric index was 80. Four weeks after its onset the icterus again began to subside. Skin grafts were applied to the stump of the leg. Three months after admission the patient developed herpes zoster of the right flank. At the end of ten days this had completely subsided, as had the jaundice. He was discharged three and a half months after entry with his diabetes well controlled.

Second Admission, two and a half years later.

The patient had been treated during the interval with several courses of tryparsamide, but both spinal fluid and blood Wassermann tests had remained positive. His diabetes was well controlled by diet alone. The stump of the leg had healed well. He had worked for a year preceding his reentry. Two days before his return he injured the small toe of his left foot. This became swollen, red, and tender.

Physical examination showed the patient to be well nourished. A few transient râles were audible at both bases. The heart was not enlarged and the murmur heard previously was still present, and in addition a diastolic murmur was now heard in the aortic area. The blood pressure was 190/80. There was a slightly infected ulcer on the left fifth toe.

The temperature was 100°, the pulse 100. The respirations were 25.

Examination of the urine showed a specific gravity of 1.025, a trace of albumin and a green precipitate with the Benedict test. The sediment was negative. The blood showed a white cell count of 5,400 and a hemoglobin of 90 per cent. The nonprotein nitrogen of the blood was 32. Hinton and Wassermann tests were positive.

X-ray examination showed slight increase in the transverse diameter of the heart, with a pressure defect in the region of the left auricle. The aortic knob appeared to be at the upper

limit of normal. The fluoroscope showed vigorous pulsation of the ventricle and aorta.

On the second day the patient developed a generalized urticaria which was relieved by adrenalin. At the end of the first week the left fifth toe was amputated. The patient responded well and was discharged afebrile two weeks later.

Final Admission, seven months later

A week before reentry, after a picnic, the patient was awakened during the night by severe pain in the anterior portion of the chest. Its location was vaguely recorded. This was followed by severe rigor. The pain continued undiminished up to admission. A few days after the onset he developed an unproductive cough which was hacking in character. Both the cough and deep inspiration aggravated the pain which later became worse in the region of the lower sternum and precordium. There was no radiation. Since the onset of his illness he suffered a severe chill each day. At one time his temperature was 104° .

Physical examination showed the presence of a pale lavender cyanosis. The patient appeared to be mildly prostrated. The skin was cold and clammy. The pulse was thready with a rate of 120. The heart appeared slightly enlarged to the left. The sounds were of very poor quality. No murmurs were audible. A_2 was greater than P_2 . The blood pressure was 80/55. At the left lung base from the angle of the scapula down there were bronchovascular breath sounds of diminished intensity accompanied by many crackling rales. The abdomen was distended tympanitic and slightly tender. There was a small gangrenous area on the left second toe.

The temperature was 102° , the respirations were 32.

Examination of the urine showed a trace of albumin. The sediment contained a few coarsely granular casts. The blood showed a red cell count of 3,400,000 with a hemoglobin of 63 per cent. The white cell count was 13,000. 78 per cent polymorphonuclears. The stools gave a positive reaction to the guaiac test. The chlorides were equivalent to 87 cubic centimeters of N/10 sodium chloride. The nonprotein nitrogen of the blood was 97.

An x-ray examination showed what appeared to be dilatation of the heart in the region of the left ventricle. The aorta was tortuous and slightly dilated. The left lung field was dull and showed hazy outlines.

The patient became quite toxic, weak and eventually semicomatose. No acetone appeared in the urine. He began to vomit and rapidly downhill and died on the third hospital day, three and a half years after the first admission.

DIFFERENTIAL DIAGNOSIS

Dr. ROBERT S. PALMER. Summarizing the first admission we have here a patient who had

known diabetes and known central nervous system lues. He came in with a septic toe and on examination had a normal cardiovascular system except for a very wide pulse pressure. It was significant that no aortic diastolic murmur was heard. He also had a few rales at one base. There was a moderately elevated temperature 102° , the pulse was only 100, I do not think he had real congestive failure. The only unusual thing in the course of this admission was that he had two attacks of jaundice, one a rather long one and no particular details are given except that it was of gradual onset and it gradually passed off. He was operated on a second time and had a recurrence of jaundice. It might be the jaundice one occasionally gets with congestive failure. I wonder if with syphilis and diabetes he did not have a so-called low reserve liver. The x-rays showed a heart of normal size and shape. We know he had central nervous syphilis. We know he had large vessel sclerosis which would explain his wide pulse pressure. Syphilis of the liver may have been present. The record does not state that he was under antiluetic treatment which could have given toxic jaundice.

He came in a second time two and a half years later. He had been under treatment with tryparsamide. His diabetes was apparently well controlled and the stump of the leg had remained all right but now he came in a second time with more diabetic gangrene. The heart was not enlarged. Again he had wide pulse pressure and this time an aortic diastolic murmur was heard in addition to a systolic murmur. Only the latter had been heard before. There was nothing unusual in the laboratory examination except that the Hinton and Wassermann tests still remained positive. The x-ray examination showed slight increase in the transverse diameter of the heart with pressure defect in the region of the left auricle. The aortic knob appeared to be at the upper limit of normal. Fluoroscopic study showed vigorous pulsation of the ventricle and aorta. That would be against there being any particular failure at the time and would be consistent with a development of regurgitation which we assume is syphilitic in origin. Of great interest is the pressure defect in the region of the left auricle. What we want to know is, was it pulsating and in the oblique position was it seen to be coming from the aorta possibly or was it a mediastinal tumor?

X-RAY INTERPRETATION

Dr. GEORGE W. HOLMES. We have one film of the gallbladder region. Apparently the patient was not given the Graham test. He has no calcified gallstones.

We have a series of films of the lower legs and feet requested. I presume to show calcification in the arteries if present and they do show some calcification. The most interesting part of the examination is the

chest This is one of the earlier films taken in 1932 That film was taken with the tube in front and the film behind, which accounts for the widening of the heart shadow and the great vessels This is a film taken at seven foot distance and it gives a much more accurate idea of the heart His diaphragm, you will notice, is high on both sides This is a gas bubble which is causing the high position of the left diaphragm That probably has something to do with the increase in width of the heart shadow, but I think it would be fair to say that the heart was somewhat enlarged and that the aorta was tortuous without evidence of dilatation In this oblique view you get a fairly good idea of the distance between the esophagus and the anterior wall of the aorta which allows us to estimate the diameter of the aorta in the region of the arch and it certainly is not much dilated I do not see sufficient evidence in these films to justify a diagnosis of luetic aortitis

DR PALMER It does not look particularly tortuous or sclerotic

DR HOLMES He was fifty-one There is a little more prominence of the knob than a man of fifty-one should have

DR PALMER There is a notch in the region of the left auricle

DR HOLMES There is no definite evidence here But I do think the auricle encroaches on the mediastinum more than it should What evidence I have is simply enlargement of the left auricle He has at this time, at least, no dilatation of the vessels in the region of the heart This is a plate taken in 1935 and here again nothing definite is found so far as the heart is concerned

DIFFERENTIAL DIAGNOSIS CONTINUED

DR PALMER So about three years after his first admission he came in for his final admission From his previous admissions, noting his diabetes, noting his syphilis and noting that he had aortic regurgitation of syphilitic origin, he has two of the things that are prone to lead to aneurysm, or to defect in the first portion of the aorta and either of which may lead to rupture of the aorta These are two possibilities I think it is unusual for a person to have chills every day, and rigors, with a temperature as high as 104° if he had rupture of the aorta into the pericardium or rupture of an aneurysm

The thing that I would like to know most and the thing that would be most important in making a differential diagnosis in this case is not mentioned, namely, the condition of his neck veins Any patient who is cyanotic, has a sudden marked fall in blood pressure, has very weak heart sounds and disappearance of murmurs previously heard, *if he does have engorged neck veins*, one can certainly say is suffering from acute cardiac compression In cases of aortic rupture into the pericardium one sees

very high venous pressures and there ought to be no doubt about the condition of the neck veins If he did not have engorged neck veins and a high venous pressure, and particularly in view of the fact that he has had chills, rigor and high temperature every day, you would think of a different process, a septic affair, possibly involving the chest, although I do not see how it would explain the sharp, severe or continued pain So we must think of metastatic sepsis from the focus on his foot Another possibility is that from the sepsis in the foot he had phlebitis and he might have had a large pulmonary embolus This might explain the fever and the chills, presumably might have given an x-ray picture which we will hear about, but I do not think the distribution and type of pain are just right

I think the last two findings in the history are consistent with infection I think perhaps the blood findings would go with either possibility

If his heart area is much increased it would be in favor of possible rupture into the pericardium The other thing is, you wonder if he could have pulmonary embolism, and acute cor pulmonale I take it he did not have any pulmonary collapse on that side or his heart would be pulled over

DR HOLMES One other possibility I think you should consider is fluid in the pericardium from rupture

DR PALMER Yes, I said that blood in the pericardium would give the picture

The urine examination makes us sure he did not die of diabetic coma anyway

From the first two admissions we know that he had syphilis and diabetes and we know that he had marked sclerosis, presumably of the large vessels, even if it does not show up particularly in the aorta In the last admission we have a history of sudden onset of severe vaguely localized upper precordial and lower sternal pain and we find a person who is cyanotic with faint heart sounds, murmurs previously well heard which disappear, a rapid pulse, plus pain, plus fall in blood pressure, and we would like to know whether or not he had a markedly raised venous pressure which is characteristic of acute cardiac compression It seems to me, though I am not certain of this, that it is not characteristic for a person to have chills and rigors for three days from blood in the pericardium Now if he has blood in his pericardium and it is acute cardiac compression, it can come from rupture of the aorta which might be due to sclerosis, syphilis, or congenital defect Coronary arteries can rupture, the auricle can rupture Those are the usual ones that give this hemopericardium I think, as I have said, that the temperature and rigor are against its being due to blood in the pericardium

Could it be due to septic pericarditis? Usually it is a complication of pneumonia or mediastinitis or something else you would know about, and whether such a thing could happen in this person from his septic foot I do not know. I think it is a possible cause of the septic sort of temperature. It seems unlikely and I do not think this possibility would fit the severe and continued pain he had in the last three days of his illness. There is nothing in the x-ray to indicate that it was due to any other compression. One can get cardiac compression from pulmonary rupture and pneumothorax. Even rare things have been reported, such as gas bacillus infection involving the mediastinum. I will say that he had general arteriosclerosis, syphilitic heart disease and will show evidence of aortitis even though dilatation does not show up by x-ray. He had aortic regurgitation and I think that he died of acute cardiac compression and that probably it is due to rupture of the aorta with blood in the pericardium hemopericardium. Where the rupture is from I do not know. It might be from the base of the aorta, from an aortic aneurysm in the first portion, or from the auricle.

I suppose one has to consider the possibility of acute coronary thrombosis and a rupture of the ventricle but I do not see any reason to ask for that in addition when you already have the possibility on the basis of lues.

A PHYSICIAN: Does "pale lavender cyanosis" mean anything or is it just another descriptive term for cyanosis? I was wondering about the blood.

DR. TRACY B. MALLORY: I should imagine it was just a combination of cyanosis and pallor as indicated.

CLINICAL DIAGNOSES

Diabetes
Central nervous system lues
Arteriosclerotic heart disease
Amputation of right lower leg and left fifth toe
Bronchopneumonia
Uremia

DR. ROBERT S. PALMER'S DIAGNOSES

Diabetes
Arteriosclerosis
Syphilitic heart disease
Syphilitic aortitis

Syphilitic aortic regurgitation
Rupture of aorta into pericardium
Cardiac compression the cause of death

ANATOMIC DIAGNOSES

Pericarditis acute fibrinopurulent
Aortitis syphilitic
Coronary thrombosis with occlusion and with out infarction, old
Cardiac hypertrophy, slight hypertensive type.
Septic infarcts of the lung bilateral.
Bronchitis, acute purulent
Hydrothorax bilateral
Pulmonary edema and congestion
Pyelonephritis left
Hydroureter, left
Cystitis chronic
Hyperplasia of prostate obstructing
Esophageal varices
Meckel's diverticulum
Arteriosclerosis, marked aortic
Operative wounds old amputation of right lower leg, amputation of left fifth toe
(Diabetes)
(Syphilis)
Septic spleen.

PATHOLOGIC DISCUSSION

DR. MALLORY: This man was quite a museum of pathology. Most of the things that he had Dr. Palmer has already suggested and I think he was quite correct in his belief that the man died of acute cardiac tamponade. It was not, however, due to blood in the pericardium but to acute purulent pericarditis. He had generalized sepsis with multiple septic infarcts in the lungs, an acute pyelonephritis and thus extensive acute pericarditis. He did have a typical luetic lesion of the aortic valve and a moderate degree of dilatation in the first portion of the aorta just above the valve with typical scarring and wrinkling which we can feel sure was due to syphilis. His left descending coronary was completely obliterated by atheroma but there was no infarction. A few of the various other findings were a hydroureter, a hyperplastic prostate, esophageal varices for which we could find no cause and a Meckel's diverticulum, though these by no means exhaust the list. The liver, gallbladder and bile ducts were all negative.

THE CHALLENGE OF THE GONOCOCCUS

THE decrease in typhoid fever, diphtheria and tuberculosis is a matter of common knowledge and gives us just cause for pride in the accomplishments of the various services that care for the public health. The incidence of gonorrhea, on the contrary, appears to have decreased little if at all. Studies by Usilton show that in the United States there are approximately 493,000 individuals constantly under treatment or observation for gonorrhea, the number of fresh infections occurring annually is 8 per 1000, which means that approximately one million cases occur each year in the whole country.

It is difficult to believe that this situation should exist without determined effort being made to find a solution. The problem presents two possible points of attack: first the prevention of infection and secondly, the rapid cure of those infected.

The first phase—that of prevention—is one

of the chief objectives of such organizations as the American Social Hygiene Association and the Massachusetts Social Hygiene Association. These societies endeavor, by means of education, to limit the number of possible exposures to infection. It has seemed to their directors unwise to attack the problem by advocating individual venereal prophylaxis.

No such scruple existed for the New York *Daily News*. This paper, stimulated by a statement made by the Health Commissioner of New York City to the effect that the prevention and treatment of syphilis was the gravest single problem facing his department, launched a campaign to give the public full and free knowledge of venereal prophylaxis. The *News* published a series of articles on gonorrhea and syphilis how to cure them and where free treatment might be obtained. These articles were reprinted bound in a pamphlet entitled "Venereal Diseases and Prophylaxis" and placed on sale at five cents a copy. This action of the *Daily News* should be welcomed by those engaged in the fight against gonorrhea and syphilis for it is generally believed that once this problem is driven out of its entrenched secrecy and into the open it can be attacked with much greater probability of success.

The second point of attack has to do with the rapid cure of gonococcus infections. Rapid cure is most essential, both to reduce the enormous economic loss incident to the disease and to prevent the infection of others, since such infection is caused largely by patients who believe themselves cured or whose infection is in a subacute stage. Yet in spite of the urgent need for improvement in the treatment of this disease, our methods are essentially the same as they have been for the past twenty years.

Not until the past five or at most ten years has there been any attempt on the part of more than an occasional bacteriologist to discover certain fundamental facts about gonococcus infections. Without knowledge of these facts, which have to do with the immunity of the host, the resistance of the gonococcus to heat, and various other aspects of the problem a rational, aggressive therapy cannot be defined.

It is encouraging to learn that at last the light of scientific research is being focussed upon this field. In 1932 the Division of Medical Sciences of the National Research Council voted favorably upon a proposal of Doctor Keves, President of the American Social Hygiene Association, that a cooperative project be undertaken with the object of promoting the study of the gonococcus and gonococcal infections. In January, 1936 the Committee appointed for this purpose, with Doctor S. Bayne-Jones as Chairman, published its first report.*

*Supplement to the American Journal of Syphilis, Gonorrhea and Venereal Diseases Vol. 20 No. 1

In this report is summarized all the important work done on this subject within the past five years, as well as certain outstanding work done previous to that period. The report is divided into two principal sections: (1) the biology of the gonococcus, including morphology, staining reactions, methods of culture, chemistry, and its resistance to physical and chemical agents; (2) gonococcal infections, including types and modes of infection, pathology, diagnosis and therapy. Material of the greatest value in laying a foundation for future research has been collected yet in reading this compilation one is impressed by the gaps still existing in our knowledge of the subject. Many encouraging leads have been opened but we still do not know why gonococcus infections clear up nor has any really valuable measure been discovered whereby we can hasten their cure. At the present writing, the methods which have been employed for the past thirty years are the ones upon which we must rely in treating the vast majority of gonococcus infections.

We do not believe that this problem any more than the problem of cancer will forever resist the investigations of scientific research. The time will surely come when gonorrhea with its attendant tragedies and economic waste will yield to a specific therapy as completely as diphtheria responds today.

THE USE OF DUST RESPIRATORS IN INDUSTRY

At the annual meeting of the American Society of Mechanical Engineers four papers* featuring the prevention of industrial diseases were presented. One of the papers by Professor Philip Drinker of the Harvard School of Public Health dealt with the uses and limitations of respiratory protective equipment. Drinker described and illustrated self-contained oxygen breathing equipment, masks supplied with fresh air, gas masks and dust respirators. The important work of the United States Bureau of Mines in developing codes for testing and certifying the performance of these various devices was stressed and industry was urged to take advantage of the Bureau's service.

It has been claimed as the result of our incomplete press release that Drinker condemned the use of dust respirators in industry. He did no such thing. Like others whose chief interest is in industrial hygiene, he emphasized that respiratory protective equipment and particularly dust respirators, are not a substitute for clean air. There are hundreds of jobs to which respirators are well adapted—they should not

be condemned as they are much too useful but they are not a substitute for clean work places. They are a second line of defence, and as such, they are used throughout the industrial world.

THE BOSTON HEALTH LEAGUE

ANNUAL MEETING

The Boston Health League on Wednesday, March 11 held its annual dinner and meeting at the Hotel Vendome. Miss Margaret H. Tracy, the executive secretary of the League reported on its activities for the year 1933 and other important events that have had a bearing on health such as the formation of the Community Federation and the Hospital Council and the organization and work of the Massachusetts State Health Commission. In addition to the regular monthly meetings of the Executive Committee, the various sub-committees have held numerous special meetings.

Seven talks to lay groups have been given by the Concer Committee and a study has been made of one hundred consecutive admissions in each of the eight cancer clinics. The Health Education Committee has sponsored a series of food exhibits demonstrating elementary principles of nutrition. The Pneumonia Committee has continued to publicize the State's pneumonia service and the Social Hygiene Committee, with the Boston Council of Social Agencies, has sponsored the monthly meetings of the Staff Council on Syphilis and Gonorrhea. The Summer Camp Committee has again issued a pamphlet in order that leaders and others responsible for children in summer camps may have available a guide for measuring to some extent equipment and standards.

Dr. William B. Keeler was introduced as Boston's new Health Commissioner and announced the following Advisory Council to the Health Department:

Dr. John W. Bartol
Professor Alexander S. Begg
Professor Samuel Prescott
Dr. Roger I. Lee
Rev. Richard J. Quinlan
Professor Wilson G. Smilie
Dr. George C. Shattuck
Dr. Hyman Morrison
Mr. Horace Morrison
Miss Gertrude Peabody

Dr. Reginald M. Atwater, Executive Secretary of the American Public Health Association spoke on "Team Work in Public Health."

The following officers were elected for the coming year:

Honorary President Dr. William B. Keeler
President Dr. John W. Bartol

*Published in full in the February and March numbers of the Journal of the American Society of Mechanical Engineers, New York, N. Y.

Vice-President Rev Robert P Barry
Treasurer Dr Richard G Wadsworth
Secretary Dr Charles F Wilmsky

EXECUTIVE COMMITTEE

Dr Gaylord W Anderson
Miss Ida M Cannon
Mrs Frederick S Dellenbaugh, Jr
Dr James M Keenan
Mr Horace Morrison
Mr Arthur G Rotch

		\$7,378 65	\$7,378 65

*The balance at the beginning of the year and that at the end appear very favorable because in December 1934 and again in December 1935 the Health League received a special donation of \$1500 to carry the work of the organization for the first three months of the next calendar year

The Massachusetts Medical Society

THE ANNUAL MEETING

"Are you planning to go to the Springfield meeting of the Society June 8, 9 and 10?"
"Too far"
"I haven't time"
"Well, I haven't thought about it"
"No, I'm sick of medical meetings, they're all the same"
How easy it is to rationalize our laziness and

indifference If the Annual Meeting served no other purpose it would still be worth while just because this annual question reminds us that our obligations extend beyond the little daily world of our own practice or our own hospital. And surely not one of us would question that they do! If all interchange of medical knowledge and thought were suspended tomorrow, how quickly medical progress would stop!

But that is considering our professional obligations in their broadest sense They may be brought much nearer home than that To our own patients and colleagues we owe the refreshed enthusiasm and new ideas awaiting us in the section meetings, exhibits, entertainments, chance encounters, and change of scene which together make up the Annual Meeting of the Society

"Yes, I most certainly am going to Springfield June 8, 9 and 10!"

BOSTON MEDICAL LIBRARY

INAUGURATES NEW SERVICE

THE Library has made special arrangements to display for its members the important new medical books as issued by all American publishers The books will be constantly changing as new books are received and will be kept on exhibit for thirty days in the Director's office on the first floor of the Library

They may be examined on application to the Director's Secretary

POSTPARTUM HEMORRHAGE

PART I

Hemorrhage that occurs after the birth of the baby, regardless of whether the placenta has been delivered, is postpartum hemorrhage. The amount of bleeding may be a prolonged trickle, the total amount ultimately reaching that point where life is threatened. Other times the bleeding is tremendous in volume almost as though one had turned on a large faucet. There is nothing so upsetting there is nothing so fearsome as serious blood loss particularly as it oftentimes occurs after the baby and placenta have been delivered and everything seems favorable.

The causes of postpartum hemorrhage are as follows:

- 1 Lacerations
- 2 The rupture of varicose veins.
- 3 Atony of the uterus.
- 4 Conditions associated with the placenta

The proper treatment of postpartum hemorrhage, of course depends upon an intelligent diagnosis. Postpartum hemorrhage from lacerations occurs as soon as the baby is born and of course has no relation to whether the placenta has separated. In the old days when accouchement forcé was an operation of daily occurrence postpartum hemorrhage from a badly torn cervix was a very common thing. Nowadays, when that operation has been intelligently cast into the discard, postpartum hemorrhage from a laceration of the cervix is a very uncommon episode. A badly scarred cervix may suffer a very deep tear in normal or operative delivery, particularly in versions when a cervix without scar would not tear so badly.

The diagnosis of a torn cervix is made by inspection. Its treatment is ligature. When a cervix has been torn badly up into the vault one must always remember the possibility of an incomplete rupture of the uterus. This if diagnosed, means laparotomy with or without hysterectomy, depending upon conditions found when the abdomen is opened. The other common site of lacerations which cause too free

* A series of short selected articles by members of the Section is being published weekly.

Comments and questions by subscribers are solicited and will be discussed by members of the Section.

bleeding are vessels lacerated anteriorly near the clitoris or posteriorly in the perineum. These should readily be diagnosed by sight and are always easily controlled by ligature.

It is always well to remember that big veins may rupture during labor or at delivery. If they are large enough they cause the loss of a tremendous amount of blood, but these again should rarely prove serious because they can readily be seen and a ligature properly placed will always control the bleeding.

Atony of the uterus means simply that the uterus has lost its normal tone, when following the birth of the placenta the periods of uterine relaxation are much longer than the periods of uterine contraction. The perfectly normal uterus, after the birth of the placenta stays firm almost all the time, relaxing very little and staying relaxed only a short time between much longer periods of contraction. An atonic uterus is oftentimes associated with precipitate labors, with cases of twins or hydramnios, where the uterine musculature has been unduly stretched, and with long drawn-out labors, and in cases where the third stage has been poorly handled.

No attempt ever should be made to crede a placenta until there have been evidences of separation, such as the descent of the cord and moderate spasmodic bleeding. Of course it is folly to allow a placenta to remain in the uterus after it has separated. On the other hand one should never attempt to crede it until one is certain separation has occurred. Provided one has had evidence of separation, that is, descent of the cord or spasmodic loss of blood associated with contractions, one is justified in attempting to crede the uterus. If the placenta has not separated entirely too vigorous attempt at crede oftentimes results in more separation, without complete separation, and much more bleeding. If the placenta does not readily come and the uterus is behaving itself, without any undue loss of blood, it is wise to leave existing conditions alone for one-half hour or an hour even and most often in this interval the placenta will be delivered naturally. I am a firm believer in having the uterus definitely held. I think that if it is held, a separated placenta lodged at the internal os, causing a good deal of concealed hemorrhage, is in this way avoided and in any case that has bled unduly I feel that the uterus should be watched carefully, until it stays practically continually in contraction, after the placenta is born.

The treatment of atonic uterus is directed toward restoring the tone of the organ. One of the most valuable procedures in the control of hemorrhage of this sort is the use of one or two minims of pituitrin intravenously. Ampules of pituitrin or ampules of the new ergot may be given intramuscularly, and there is no real limit to the amount of these drugs that may be

so used. Occasionally an atonic uterus has to be packed, but fortunately this is rare.

Intelligent knowledge of how the uterus behaves after the birth of the baby is necessary to diagnose and treat postpartum hemorrhage due to any pathology associated with the placenta. This means that the uterus must be carefully held after the birth of the baby.

Part 2 will appear in next week's *Journal*.

THE TREASURER'S REPORT

COVERING REFUND DISTRIBUTION

THE Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to District Societies for 1936.

The Council voted to distribute the sum of \$5000 to District Societies. The total number of payments of annual dues received by the Treasurer, by March 2 to be counted for the refund, was 3516. Therefore the refund to the District Societies for each paid Fellow is \$1.422.

The following table gives the number of payments in, and the refund to, each District.

District	Number Reported Paid	Check
Barnstable	42	\$59.74
Berkshire	83	118.04
Bristol North	58	82.50
Bristol South	155	220.42
Essex North	149	211.89
Essex South	169	240.33
Franklin	37	52.61
Hampden	204	290.10
Hampshire	42	59.74
Middlesex East	84	119.47
Middlesex North	93	132.26
Middlesex South	696	989.72
Norfolk	602	856.05
Norfolk South	83	118.04
Plymouth	98	139.38
Suffolk	528	750.52
Worcester	321	456.47
Worcester North	72	102.40
	3516	\$5000.00

In 1935, for comparison, the total number of payments for the refund was 3279.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the
Committee for the week beginning April 12

Berkshire

Thursday April 10 at 4 30 P.M. at the House of
Mercy Hospital Pittsfield. Subject: Diseases
of the Liver — Surgical Problems in
Diagnosis of Acute Disease of Gallbladder
and Liver. Instructor H. M. Clute. Mel-
vin H. Walker Jr. Chairman

Bristol North

Wednesday April 15 at 7 30 P.M., at the Mor-
ton Hospital Taunton. Subject: Lung Dis-
eases (Medical) — (a) Differential Diagnosis
and Treatment of Lobar Pneumonia (b)
Symptoms and Signs in Chronic Lung Dis-
ease Tuberculosis Bronchiectasis etc. In-
structor T. L. Badger. Arthur R. Crandell
Chairman

Bristol South (New Bedford Section)

Friday April 17 at 4 00 P.M. at the St. Luke's
Hospital New Bedford. Subject: Pediatrics
(Surgical) — Abdominal Disease in Child-
hood. Instructor W. E. Ladd. Harold E.
Perry. Chairman

Franklin

Wednesday April 15 at 8 00 P.M., at the Frank-
lin County Public Hospital Greenfield.
Subject: Cancer of Breast and Uterus.
Instructor G. A. Leland. Halbert G. Stetson
Chairman

Middlesex North

Friday April 17 at 7 00 P.M., at the Lowell
General Hospital Lowell. Subject: Acute
and Chronic Nephritis. Instructor J. P.
O'Hara. Leonard C. Dursthoff. Chairman

Norfolk

Friday April 17 at 8 30 P.M. at the Norwood
Hospital Norwood. Subject: Review of Re-
cent Progress in Medicine. Instructor
L. M. Harxthal. H. B. C. Riemer. Chairman.

Worcester (Milford Section)

Wednesday April 15 at 8 30 P.M. at the Mil-
ford Hospital Milford. Subject: (a) Can-
cer of Stomach and Bowel. Modern Care of
Inoperable Cancer (b) Cancer of Genito-
Urinary Tract. Instructors E. G. Crab-
tree and C. C. Luud. Joseph I. Ashkins
Sub-Chairman

MASSACHUSETTS LEGISLATIVE NOTE

HOUSE BILL 1035

In this bill Frank L. Whipple, Henry E. Oxnard,
John Hall Smith, Horatio S. Card, Herbert Hitchcock,
Howard C. Gale, John M. Russell, their associates
and successors ask to be constituted a body cor-
porate under the designation of the "Trustees of
Middlesex University" and that they and their suc-
cessors and others to be elected members of the
Corporation shall remain a body corporate by that
name forever. The duties of this corporation are
set forth together with its educational functions
and specifically the authority to confer degrees which
other colleges and universities have.

The Middlesex College and University of Mass-
achusetts Inc. are authorized under the bill to
transfer to the Middlesex University the various
schools now maintained by these two institutions.
All franchises, property, claims, trusts and estates
now held by them and after these transfers the Mid-
dlex College and the University of Massachusetts
will pass out of existence except as the Middlesex
College may be a department of the Middlesex Uni-
versity.

The report of the Department of Education of
Massachusetts by the Commissioner James G. Rea-
don recommends that this petition be not granted.
Since the attitude of Commissioner Reardon is evi-
dently founded on a study of the University of Mas-
sachusetts and its component institutions his opinion
should be given due weight.

MISCELLANY

LARGE ATTENDANCE EXPECTED AT POST GRADUATE INSTITUTE

Provision has been made for an expected attend-
ance of at least 1,000 at the Philadelphia County
Medical Society's Postgraduate Institute to be held

In the Bellevue-Stratford Hotel, Philadelphia, April 20 to 24, inclusive

Response to the preliminary announcements has exceeded the committee's expectations. Letters of inquiry have been received from physicians in twenty-five states—as far west as Missouri, as far south as Alabama and as far north and east as the New England States.

In view of the widespread interest in this initial effort by the county society of an outstanding medical center to provide advanced instruction for practicing physicians, it is virtually certain that the Institute will become an annual event.

This year's program, dealing entirely with cardiovascular and renal diseases and their far-flung ramifications, is being presented by fifty-three leading members of the faculties of the University of Pennsylvania School of Medicine and Graduate School of Medicine, Jefferson Medical College, Temple University School of Medicine, and the Woman's Medical College of Pennsylvania.

Registration, open to all physicians who are members of their local county medical societies, will begin at 10 A. M., Monday, April 20. The only charge is \$5.00 to help defray the expenses of the Institute. Following a luncheon in the hotel, the scientific program will get underway at 2 P. M. Morning and afternoon sessions will be held on Tuesday, Wednesday, Thursday and Friday. There is no division of the program into sections. One paper will be read at a time, and all attending will be able to listen to the entire program.

In addition to the program there will be an interesting arrangement of technical exhibits in adjoining rooms, covering a wide range of articles used by the physicians or their patients.

The detailed program may be secured on application to Dr. Henry G. Munson, 4935 Catherine Street, Philadelphia.

THE NEW YORK HOSPITAL PLAN

The Executive Director of the Associated Hospital Service in and about New York City has disclosed that this organization will have 10,000 persons enrolled within a short time and expects to offer a special family membership plan very soon. In order to enlarge this scope of the service, studies of actual facts are underway.

The treasurer of the service reported that the three cents a day plan had invested \$101,844 in U. S. Treasury bonds and that all expenses had been met promptly. One hundred and seventy-four hospitals in the metropolitan area are giving service under the plan.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

DIVISION OF ADULT HYGIENE

Number 33 Cancer Clinic Bulletin April 1, 1936

Due to the large number of requests from physicians for suggestions regarding public speeches in

the Coöperative Cancer Control Committees, we are publishing sample addresses written by different physicians in the bulletins of April, May and June.

The cancer problem comes home to every one of us because once past the age of forty, one out of every eight may expect to die of this disease, unless our present handling of the problem can be improved. This means that hardly a family is exempt. More than any other disease, cancer is a difficult one to treat because of the insidiousness of its onset, the difficulty of accurate diagnosis, the virtual impossibility of treatment in certain localities and the long period of painful illness involved. The three methods of treatment available are all costly, whether it be surgical, high voltage x-ray machines, or the use of radium. This cost rests on the community as well as the individual.

We are not all concerned with the treatment of cancer, but we are all concerned with its early recognition, because cancer is at first a local disease restricted to one organ or portion of an organ, and later becomes widely disseminated throughout the body. At this time cure is obviously impossible. The time, then, at which cancer can be most successfully treated is while it is still local. To establish diagnosis at this period, the medical profession must have the coöperation of all, because unless a person comes for diagnosis and treatment early, it is apt to be too late. The time to start treatment of cancer is as soon as possible after symptoms have appeared. Consequently all must be on the alert for the danger signs of the disease.

The most obvious and important of these symptoms is a sore which does not heal, a lump, particularly in the breast, or abnormal discharge of blood from any of the body cavities. These are not necessarily symptoms of cancer, but they should lead one to a physician in order to determine whether they are dangerous. Only through the alertness of each person can the present heavy toll of cancer be reduced.

One of the reasons that cancer is so insidious is that it is a disease of the body's own cells. It is not an invader attacking from without, but a treacherous change of one's own tissues. The essence of cancer is an abnormal uncontrolled growth of cells. These cancerous cells have a power of invading all parts of the body and may be carried there by the blood or the lymph stream as blazing brands are carried by the wind in a conflagration. Wherever these cancer cells may lodge, they grow true to their initial type and their behavior remains the same. Thus if we have a cancer develop in the stomach, its secondary deposit or metastasis will look like the cells of the stomach whether they occur in the lungs, liver or bones. This power of spread is what makes early treatment of cancer so essential. Obviously the disease can be treated while it is local, but once it has become disseminated to other organs, treatment is virtually hopeless.

Often the question comes up as to what causes cancer. In all probability, there is no one cause. The search for a single cause is as hopeless as that

for the philosopher's stone. There are a number of causes for cancer some of these we know others we do not know. We know that there are certain complex hydrocarbon substances which can be developed from coal tar products that have the power of producing cancer to an extraordinary degree. If one takes certain of these substances and applies them to the skin of a mouse or rat or injects them into the tissue beneath the skin a cancer will develop at the site of application within a few weeks. These so-called carcinogenic substances are somewhat related as regards their chemical formulae. Their mode of action is apparently through causing continued destruction of tissue with repeated efforts at repair so that one has a continuous active growth of cells which ultimately will develop into cancer. It has long been known that workers handling aniline were particularly apt to develop cancer. Many of you will remember the cancers that developed to the New Jersey girls who swallowed minute amounts of radio-active compounds in the course of painting luminous dials on watches.

The early workers in x-ray give us still another example of a means by which cancer can be produced. These men enthusiastic over the great benefits that the x-ray gave in establishing diagnosis, were alert only to its good features and did not realize the danger of repeated exposure to so powerful a force. As a result, most of the pioneer workers in the field have developed cancer of the skin at various points exposed to the x-rays particularly the hands. There is but little danger attached to a single exposure but repeated exposures are dangerous.

Many of the cases of cancer can be traced to what is called chronic irritation that is repeated injuries to various tissues of the body and attempts of the cells of which these tissues are made up to repair the injuries. We may say that cells have two chief aims, one to multiply the other to function. Normally a balance is maintained between these two. With repeated attempt of repair and growth the function of multiplication becomes more and more improved until the cell runs wild so to speak and multiplies rapidly at the expense of the adjoining structures. This in essence is a cancer. Instances of cancer due to chronic irritation are constantly presented. Cancer may develop in a long-standing sore of the cheek caused by a jagged tooth or an ill-fitted plate. Cancer of the intestines may develop in a polyp subject to irritation. Cancer of the skin may develop at the edge of a varicose ulcer. One of the most interesting forms of cancer due to chronic irritation is that provided by a tribe in the vicinity of Kashmir in India. This tribe lives in a high altitude. They are nomads. Consequently in the absence of houses in which to shelter themselves they carry beneath their clothing an earthenware pot which is filled with glowing charcoal (in order to keep warm). Not infrequently they develop tumors of the abdominal wall from this so-called "kangri" basket, and in the site of these tumors cancer very frequently develops.

Chronic irritation, then we may consider as one cause of cancer. The tissue changes brought about by exposure of x-ray and radium under certain conditions we can regard as a cause of cancer. In lower animals there are certain types of cancer which develop as a result of parasitic virus infection and there are those who have attempted to ascribe human cancer to the action of a virus but this is regarded as definitely unlikely.

Heredity has been spoken of as still another cause. We know enough from work with animals to realize that heredity may play a part. We know we can breed a strain of animal in which tumors develop and another strain in which they rarely develop. But these strains must be carefully inbred over long periods of time and as long as human beings select their mates for looks, brains or wealth there will be no chance of getting at the cancer problem from the angle of heredity. Moreover before heredity can be surely established as a cause of cancer we should have accurate records for at least fifteen or twenty generations. With all our science and with all the progress that medicine has made there are few people who can tell what all four of their grandparents died of let alone their great grandparents. Probably two or three centuries must pass before we can get accurate information as to hereditary cancer in human beings.

We do know however that certain people are more susceptible than others to cancer and that a person who has had one cancer is for more likely to develop a second even though the first may be cured than is a person who has had no cancer. There is then a definite susceptibility to cancer but what determines that susceptibility we cannot say. The experimental work done on lower animals has been and is a tremendous help in solving various phases of the cancer problem. Cancer can be transplanted from one animal to another and placed in any locality desired so that its effect can be studied and the most safe treatment be developed.

The question is often raised as to whether cancer is contagious whether there is any possibility of getting cancer while nursing a patient who has cancer or in using the same article which he has used. There is none because cancer can be transmitted only through the direct inoculation of tumor cells from one living body directly to another and even this practically never occurs in human beings although with suitable operative procedures it can be carried out in animals. The one outstanding point for us to keep continually in mind is that if we are to prevent the tremendous amount of human suffering and economic loss entailed by this disease we must recognize it early and treat it vigorously.

CERTIFIED MILK REPORT OF THE MEDICAL MILK COMMISSION OF BOSTON FOR 1935

The Medical Milk Commission of Boston Inc. submits this report of its activities during 1935 in the hope that a glance at its contents will make the reader realize that present-day Certified Milk is a far

better and safer product than that in bygone years. The members of the Commission believe that in its raw state the milk is as nearly safe as is humanly possible and when pasteurized it is the best milk obtainable anywhere.

Certified Milk is produced under the regulations of the Massachusetts Department of Public Health and the annually revised Methods and Standards of the American Association of Medical Milk Commissions. These form the strictest code of milk produc-

Units per quart until December, 1935, when the new U S P Vitamin D units were followed (160 Steenbock Units equal 430 U S P Vitamin D units). In the fall of 1934 the manufacturer of the irradiated yeast advised the farms to reduce slightly the amount of yeast fed, with the result that Hampshire Hills fell below the established standard in the November test and Cherry Hill and Walker Gordon in the February test. The Commission immediately ordered the farms to resume the earlier dosage and

TUBERCULIN TESTS FOR 1935

Name of Farm	Date of Test	Number of Cows Tested	Number of Reactors	Per Cent of Reactors
Cherry Hill	August 17, 1935	181	3*	1.66
Hampshire Hills	January 19, 1935	230	0	—
Walker Gordon	April 4, 1935	363	0	—
Total		774	3	0.39

*No visible lesions on postmortem examination. Accredited herd certificates continued by Bureau of Animal Industry.

tion with which we are familiar. We believe that our producers are in good faith trying to live up to the code. If we did not so believe, we would not be willing to grant them our certificate.

The herds are all accredited, that is, free from tuberculosis according to the tests and rules of the Federal Bureau of Animal Industry.

They are almost free from contagious abortion (Bang's Disease). Of 1433 samples of blood tested during the year only two gave a positive agglutination test. These animals were immediately removed from the herds.

forbade them to vary the dosage in the future without our permission.

We believe that "Vitamin D Milk" containing 430 U S P units per quart is as adequate an antirachitic agent as cod liver oil or Viosterol in their usual dosage and that it is more palatable, convenient and likely to be taken by the patient. It must be sharply distinguished from irradiated milk which contains only 50 Steenbock or 135 U S P units of Vitamin D per quart.

The health of the cows is supervised by Dr. W. T. White, a veterinarian appointed by and responsible

AGGLUTINATION TESTS FOR 1935

Farm	Date	Total Samples	Negative	Positive	Doubtful
Cherry Hill	January	161	158	0	3
	May	182	152	0	30
	July	180	166	0	14
	September	179	164	1	14
Hampshire Hills	May	217	193	0	24
	December	225	216	1	8
Walker Gordon	June	289	260	0	29
		1433		2	

The feed of the milking cows is selected with the ideal of maintaining optimum mineral, protein and vitamin content in the milk the year round and not solely from the point of view of maximum milk and butterfat output.

The feed of approximately three quarters of the cows is specially reinforced by the addition of irradiated yeast. Bio-assays of the resulting Vitamin D Milk are made for the Commission by Professor J. W. M. Bunker of Massachusetts Institute of Technology. The results were reported in Steenbock

to the Commission. No serious conditions among the herds were discovered during the year.

The health of the men is supervised by physicians living near the farm. These men are appointed by and are responsible to the Commission. They make a physical examination of all new employees before they are allowed to handle milk. This examination includes cultures from the nose and throat and of the stools. They also see immediately all sick employees and quarantine or exclude from contact with the milk any men with diseases possibly transmissible.

BIO-ASSAYS FOR VITAMIN D

Name of Farm	Oct. 1933 Steenbock Units per quart	March 1934 Steenbock Units per quart	Nov., 1934 Steenbock Units per quart	Feb., 1935 Steenbock Units per quart	Dec., 1935 U S P Units per quart

Hampshire Hills	109	3	11 800 15 700 19 100
Walker Gordon	109	3	11 500 11 900 19,200

Summary—Certified Milk Raw

	Times	Per Cent
5 000 and below	231	85.93
5 001 through 10 000	36	11.01
	317	96.94
10 001 through 15 000	7	2.14
15 001 through 20 000	3	.93
Over 20 000	0	0
	397	100.00

CERTIFIED MILK PASTEURIZED

Name of Farm	Number of Bacteria Counts	Counts of —100	Counts of 100	Counts of 200	Counts of 300	Counts of 400-700	Counts of Over 700	High Counts in Detail
Cherry Hill	98	67	23	4	2	2	0	500 600
Hampshire Hills	107	82	22	3	0	0	0	
Walker Gordon	106	69	29	7	1	0	0	

Summary—Certified Milk Pasteurized

	Times	Per Cent
Counts of less than 100	113	70.00
Counts of 100	74	93.80
	29	93.89
Counts of 200	14	4.50
Counts of 300	3	.96
Counts of 400-700	2	.65
Counts of over 700	0	—
	311	100.00

through milk During 1935 there were no serious diseases reported although a number of minor infections were so excluded

Bacteria counts are the best laboratory check we have on the conditions under which milk is produced and handled Our samples are collected by our agent from the distributing depots and delivered to the laboratory of the Department of Comparative Pathology at the Harvard Medical School where the counts are made The standard plate method is used except that 6 per cent defibrinated horse blood is added just before the plates are poured This enables the laboratory to detect the presence of hemophilic organisms, but has the disadvantage of giving counts approximately 20 per cent higher than those obtained by the unmodified standard plate method

One of the requirements for Certified Milk is that it shall be bottled on the farm where it is produced The same rule applies to pasteurization Each farm has its own pasteurization outfit which is used for no other grade of milk Cherry Hill and Walker Gordon pasteurize in holding tanks and then cool and bottle Hampshire Hills pasteurizes in the bottle

"Methods and Standards for the Production of Certified Milk" state that the milk shall contain not over 10,000 bacteria per cubic centimeter, and after pasteurization not more than 500 per cubic centimeter In 327 counts of Certified Milk Raw only 3 per cent of these counts were over 10,000 bacteria per cubic centimeter and 86 per cent were 5,000 and under In 311 counts of Certified Milk Pasteurized in only one count was it over 500 bacteria per cubic centimeter and in 94 per cent the counts were 100 or less

AN HONOR TO THE MEMORY OF DR NATHAN COOLEY KEEP

As an especial feature of the annual Alumni Day or joint clinical meeting of the Harvard Dental Alumni Association and the Harvard Odontological Society, April 3, 1936, a portrait of Dr Nathan Cooley Keep was unveiled in Vanderbilt Hall, the gift of the artist, Mrs Marie Danforth Page, whose husband is a grandson of Dr Keep The portrait was unveiled by Miss Elizabeth Keep, the great granddaughter of Dr Keep Dr Leroy M Miner received the portrait in behalf of the school and Mr Henry L Shattuck,

Treasurer of Harvard College, accepted it in behalf of the Harvard Corporation

Dr Keep graduated from the Harvard Medical School in 1827 and practiced dentistry in Boston for many years He was interested in the founding of the Massachusetts Dental Society, serving as its first president and the first dean of the Harvard Dental School

SOCIAL SECURITY BOARD APPROVES PUBLIC ASSISTANCE PLANS OF OHIO, MASSACHUSETTS, ARKANSAS, VERMONT, WASHINGTON AND OKLAHOMA

The Social Security Board approved public assistance plans of six States on March 31 the Arkansas State plans for aid to the needy aged, the blind and to dependent children, the Vermont State plans for aid to the blind and dependent children the Washington State plan for aid to the blind, the Ohio State plan for aid to the needy aged, the Massachusetts State plan for aid to the needy aged and the Oklahoma State plans for aid to the needy aged and to dependent children

As a result of the Board's action these States will receive allotments of funds from the Federal Government to match their own expenditures for assistance to the needy aged, dependent children, and the blind The Federal grant will be as much as the States themselves spend in the case of assistance to aged persons and aid to the blind, up to a combined total of \$30 a month per person, plus 9 per cent of the amount of the Federal grant to help cover the States' administrative expenses For aid to dependent children the Federal grant to States with approved plans will be one dollar for every two dollars the State spends, up to a combined total of \$18 per month for the first dependent child in any one family and \$12 per month for each additional child in the family

This approval by the Social Security Board brings the number of States with approved public assistance plans to 27 in the case of aid to the needy aged, 18 for aid to the blind and 17 for aid to dependent children Almost 500,000 individuals are affected by these plans, 390,000 aged men and women, 86,187 dependent children and 17,543 needy blind

The public assistance plans approved on March 31 are expected to provide aid to 91,167 aged persons in Ohio, 25,600 aged persons in Massachusetts 11,000 aged, 300 blind persons and 550 dependent children in Arkansas, 175 blind persons and 577 dependent children in Vermont, and 700 blind persons in Washington

In Massachusetts the average rate is \$25.55 per person Payments to the blind in Vermont are estimated at an average rate of \$11.50 per month to each individual and payments to dependent children at \$9 per month

To be approved by the Social Security Board, under the terms of the Social Security Act, a State public assistance plan must provide for cash pay

ments to needy aged persons to dependent children living with relatives, or to the needy blind in all parts of the State. A single State agency must administer the plan or supervise its administration if

it is directly administered by the Counties. This State agency must grant the opportunity for an appeal from the decision of any county deaying assistance to an applicant.

AFFAIRS IN CONNECTICUT

SILICOSIS IN CONNECTICUT

Vernon A. Zimmer, director of the Federal Bureau of Labor Standards, created considerable discussion in

Connecticut recently by stating that approximately 133,300 or 37 per cent of Connecticut industrial workers are exposed daily to industrial silicosis. In the same statement Mr. Zimmer branded the Connecticut state compensation law "inadequate and

unfair' both to workmen and employers as to its silicosis provisions

All this controversy has arisen as an aftermath of the recent revelations of its prevalence among the unfortunates who are employed on the Gauley Bridge, West Virginia, tunnel project. Mr Zimmer makes a point of the fact that the Connecticut compensation laws make no special provision for silicosis. To mention specifically the occupational diseases for which compensation can be awarded would weaken the laws, for it would be virtually impossible to list by name all of the diseases that may result from employment. Instead, the law declares that wherever "personal injury" appears it shall be construed to include "occupational disease," and occupational disease itself is defined as "a disease peculiar to the occupation in which the employee was engaged and due to causes in excess of the ordinary hazards of employment as such. Under that definition not only the sufferer from silicosis but those affected with glass blower's cataract, miner's ankylosis, pitch cancer, caisson disease, etc., are protected.

Mr Zimmer also stated that silicosis, because of its special effect on workmen, cannot be compensated for as are other industrial diseases. The 1935 session of the Connecticut Legislature made one important change in the Compensation Code which provides that an application may be filed at any time within a year after the first manifestation of an occupational disease, and defines "first manifestation" as the first appearance of the effects of the disease "in such manner as is or ought to be recognized by him (the employee) as symptomatic of the occupational disease for which compensation is claimed." Mr Zimmer apparently was not aware of this recent change in the Code.

It is difficult to see how any serious silicosis condition could exist in Connecticut, provided the laws are properly administered. The Health Code of the State provides that all occupational diseases must be reported by the physician in attendance, to the State Department of Health. An investigation by the State Department follows. In the event that conditions dangerous to the health of the workers are found the installation is required of protective devices or such other measures as may be necessary to safeguard the employees. Connecticut's compensation laws as they apply to industrial diseases are among the most advanced in the country. In fact, the Compensation Code as it exists in Connecticut today has been urged on states possessing lower standards as a model on which to pattern their own laws.

The federal bureau of labor recommends the following standards for employers:

(1) Prevention of silicosis lies entirely in keeping the dust from getting into the air, and therefore, prevention is mainly an employer's problem.

(2) Control of dust at the point of origin by the use of local exhaust systems or wet methods, or a

combination of both. Wetted dust may dry out and reenter the air, therefore dust must be removed and disposed of.

(3) General ventilation will help reduce silica concentration which should never exceed 5,000,000 particles of pure silica per cubic foot.

(4) Clean floors, walls and benches regularly by vacuum, or wet brushing and sweeping, and preferably outside of working hours. Wet down foundry floors at frequent intervals.

(5) Have sand blasting done only with articles completely enclosed or protect workers by positive pressure masks.

(6) Have medical examinations, with lung x-rays, of employees at intervals not exceeding one year. Remember that most workers with simple silicosis may safely continue at work if the dust hazard is removed.

(7) Make dust surveys and analyses frequently to determine exactly the dust hazard of the plant.

ANNUAL MEETING OF HARTFORD MUNICIPAL HOSPITAL

James C. Wilson, M.D., was elected president of the staff of the Municipal Hospital at its annual meeting on March 3, 1936, to succeed Anthony W. Branon, M.D. A new office was created, that of vice-president, and to this office Harry L. F. Locke, M.D., was elected. Walter L. Hogan, M.D. was elected secretary. New appointments and promotions included the following: James E. Davis, bronchoscopist; H. N. Hurwitz, orthopedist; A. Samponaro, otolaryngologist; Milton F. Little, ophthalmologist; Elliot S. Cogswell, roentgenologist; Louis H. Gold, assistant neuropsychiatrist; Edgar Butler and J. L. Gothers, assistant dentists; Philip Adelman and A. R. Schwartz, assistant ophthalmologists and otolaryngologists; J. R. Glazier and J. F. McGrath, assistant surgeons; Charles Bingham, assistant physician; C. J. McCormack, assistant gynecologist; E. H. Crosby, assistant orthopedic surgeon; H. M. Glaubman, assistant pediatrician.

INFANT MORTALITY

The State Department of Health has announced the infant mortality for 1935 in Connecticut to be 43.2 under one year of age per 1000 births. Actually there were 944 deaths and 21,860 living births in 20 years, from 1916 to 1935, the death rate for infants under one year of age has dropped from 100.8 to 43.5. More than one half of the deaths occurred during the first week after birth, and of these the greater part occur the first day. The greatest single cause of death is prematurity.

FEDERAL FUNDS RECEIVED

On March 2, 1936 Governor Cross received from the Social Security headquarters at Washington a check for \$6,379.16, the first installment of a contribution the Federal Government is making for the extension of maternal and child care under the Connecticut State Department of Health. Dr. Os-

born State Health Commissioner recently expressed the hope that these funds will permit the State among other activities to undertake a broad study of cancer control. Already there is a statute authorizing the State Department of Health to make certain investigations concerning the prevention and treatment of cancer and to take such action as it may deem of assistance in bringing about a reduction in mortality from this disease.

Connecticut has made decided progress in cancer prevention work but it has not developed as unified and comprehensive a plan as has Massachusetts in the past ten years. The Connecticut State Medical Society in addition to supporting the cancer control act, has formed a special tumor committee under the chairmanship of Dr. Thomas H. Russell of New Haven. As a result of this committee's work there are now nine or ten cancer clinics in operation in the State and work in research and publicity is progressing.

TITLE OF NORWICH HEALTH OFFICER CHALLENGED

Dr. Harrison Gray, Health Officer of Norwich for a four-year term up to October 1, 1935, claims the appointment to the office on November 4, 1935, by County Health Officer Richard L. Norman and his claim was substantiated by Judge Allyn M. Brown in Superior Court. Dr. Albert Quintiliani has appealed from Judge Brown's decision to the Supreme Court, claiming that he was appointed by Mayor Moran on the same day and the appointment confirmed by Court of Common Council. Dr. Quintiliani's appointment seems to have missed out by a few hours.

CONNECTICUT MUTUAL LIFE INSURANCE COMPANY PAYS TRIBUTE TO DR. CHARLES D. ALTON

On March 2, 1936, Dr. Charles D. Alton, sixty years old, was tendered a dinner at the Hartford Golf Club by the official staff of the Connecticut Mutual Life Insurance Company. This occasion marked the completion of sixty years of continuous service by Dr. Alton. James Lee Loomis, president of the company and toastmaster at the dinner, lauded the "splendid fidelity" of Dr. Alton in discharging his duties with the company over more than half a century, praised the retiring medical referee's rare philosophy of life and his "internal resources of character" and presented to him the company's service medallion with a specially inscribed bar in token of his sixty years of service. A gift of a morocco portfolio containing some three hundred testimonial letters from friends in the life insurance business and medical profession was presented to Dr. Alton, also a silver tray equipped with decanter and wine glasses, the bottom of the tray being inscribed with the names of the officers of the company.

Dr. Alton in his remarks narrated the difficulties the company experienced in its early days in ab-

taining competent medical examiners in those places where the physicians "knew nothing of insurance and hardly more about medicine. In a few words he painted "the sombre heaviness of Savannah Ga. during a trip he made there in 1877 when a yellow fever epidemic was lifting. Humorously Dr. Alton described some of the adventures that comprised the "routine" of his early days as medical examiner for the Connecticut Mutual referring to the manner in which he built up the company's field medical examining resources.

Dr. Charles D. Alton has been active in medical circles, being a past president of both the Hartford Medical Society and the Hartford County Medical Association. He was also formerly vice-president of the American Climatological and Clinical Association.

RECENT DEATHS

BATEMAN—FRANK E. BATEMAN, M.D., of 163 Highland Avenue, Somerville, Massachusetts, died at his home, April 5, 1936. Dr. Bateman was born in Fitchburg, Massachusetts, in 1866. After graduating from the Harvard Medical School in 1894, he began practicing in Charlestown but after four years moved to Somerville.

Dr. Bateman was a Fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, Mrs. Sophia C. Bateman, two daughters, Mrs. Robert Jones of West Medford, and Miss Sylvia Bateman of Somerville, and a son, Leon W. Bateman of West Acton, survive him. There are also five grandchildren.

BONGIORNO—FELICE BONGIORNO, M.D., died at his home in Waltham on February 20, 1936. Death was due to coronary thrombosis.

Dr. Bongiorno was born in Malta, Italy, on June 14, 1893. He was educated in Italy and served with the Italian Medical Corps for five years, being wounded once and receiving the Croix de Guerre. He graduated in medicine from the University of Naples in June, 1919, coming to this country in 1922 and locating in Waltham, Massachusetts, at that time. He was licensed to practice medicine in the State of Massachusetts in 1923 and he became a Fellow of the Massachusetts Medical Society in 1928.

He was married in 1930. Dr. Bongiorno is survived by his widow, nee Rosanna Gaudreau, and two children.

BARRETT—ALBERT MOORE BARRETT, M.D., formerly associated with the Massachusetts Department of Mental Diseases, died at his home in Ann Arbor, Michigan, April 2, 1936. He began his career in the field of Mental Diseases and served on the staff of the Iowa State Hospital for the Insane. Dr. Barrett then went to the Danvers (Mass.) Hospital for the Insane and after serving there about four years,

was advanced to the position of Assistant Psychiatrist at the Worcester Insane Hospital

In 1906 he was called to the University of Michigan and became the organizer of the first university hospital and clinic for mental diseases in the United States. This institution was a part of the University of Michigan and Dr Barrett had been the Professor of Psychiatry at this University Medical School since 1920.

He had been president of the American Psychiatric Association, the American Neurological Association, and the Psychological-Pathological Association. A son, Edward Bowman Barrett, survives him. His wife, Mrs Eliza Jane (Bowman) Barrett, died several years ago.

NOTICES

AN EXHIBIT OF ATHLETIC SCULPTURE BY DR R TAIT MCKENZIE

Dr R Tait McKenzie of Philadelphia will exhibit his conceptions of artistic athletic development at the Doil and Richard's Gallery, 138 Newbury Street, Boston, from April 12 to April 25, 1936.

Dr McKenzie has an established reputation in the field of physical education and during the World War organized the first rehabilitation camps in England, United States and Canada.

BOSTON UNIVERSITY SCHOOL OF MEDICINE SURGICAL CLINIC AT THE BOSTON CITY HOSPITAL

Friday, April 17, 12 1, Cheever amphitheatre

Dr Richard H Miller, Assistant Professor of Surgery, Harvard Medical School, and Visiting Surgeon, Massachusetts General Hospital, will speak on Acute Abdominal Pain.

Physicians and medical students are invited.

THE NATIONAL TUBERCULOSIS ASSOCIATION

The National Tuberculosis Association has a membership of physicians, nurses, health workers, public spirited citizens and other individuals and agencies which furnish to it a means for moral support of its work. Membership in the National Tuberculosis Association is semiprofessional. Individual membership is open to anyone who wishes to join. The membership fee for regular individual membership is \$5 00 a year. The Association also has associate memberships at \$10 a year, sustaining memberships at \$20 a year, and life memberships at \$100. All members of the Association are given free a subscription to the monthly Bulletin of the National Tuberculosis Association, the annual volume of Transactions containing papers read at the annual meeting or a choice of several other publications. An application card for membership will be sent on request. Checks should be made payable to Collier Platt, Treasurer, and sent to 50 West 50th Street, New York, N Y.

CALENDAR OF LECTURES AND RADIO TALKS LISTED IN BOSTON HEALTH LEAGUE OFFICE —APRIL, 1936

April 13—*Self Measurement as a Group Guidance Technique*—Richard D Allen Sponsor, B U School of Education 29 Exeter Street 7 15 P.M. \$1 50

April 14—*Metabolism*—WBZ, 4 45 P M Sponsors, Massachusetts Medical Society and Massachusetts Department of Public Health

April 14—*Preparation for Vacation*—Sponsor, Class Rm Teachers' Sect, New England Health Education Association Emma Rogers Room, M I T Supper at 6 P M, 60c, talk at 7 P M

April 14—*Leanness and Fatness in Terms of Body Build*—Dr S J Thannhauser Sponsor, Massachusetts Dietetic Association 8 P M 46 Beacon Street Non members 25c

April 16—*State Private Duty Nurses' Dinner*—Sponsor, Massachusetts State Nurses' Association. 6 30 P M Hotel Bancroft, Worcester Ticket for dinner and transportation, through Alumnae

April 21—*Health of the School Child*—WBZ, 4 45 P M Sponsors, same as April 7 and 14

April 21—*Field Trip, E L Patch Company*—Sponsor, Massachusetts Dietetic Association 46 Beacon Street 2 P M

April 21—*Some Fallacies in Social Hygiene Teaching*—Dr Helen McGillicuddy Sponsor, Full Time Teachers' Sect, New England Health Education Association Emma Rogers Room, M I T Supper at 6 P.M., 60c, talk at 7 P.M.

April 27—*The Problems of the Adolescent*—Augusta F Bronner, Ph D Sponsor, B U School of Education 29 Exeter Street 7 15 P M \$1.50

April 28—*Cosmetics and Common Sense*—WBZ, 4 45 P M Sponsors, Public Education Committee of Massachusetts Medical Society and Massachusetts Department of Public Health

Tuesdays 1 30 P M —*Health Review*—Courtesy WEEL Sponsor, Massachusetts Department of Public Health

Fridays 4 45 P M —*Health Forum*—Courtesy WEEL Sponsor, Massachusetts Department of Public Health

INTERNATIONAL CARDIOLOGICAL MEETING ROYAT (AUVERGNE) ASSEMBLY OF PHYSIOLOGISTS PATHOLOGISTS AND THERAPEUTISTS, MAY 31 JUNE 1, 1936

Various professional groups of Royat, namely, the Medical Society, the Mineral Water Company, the Publicity Commission, the Hotel Syndicate, the Local Information Bureau and the Municipalities, have decided to organize at regular intervals International Cardiological Meetings to be held at Royat. Questions will be discussed at each meeting from

the physiological, pathological and therapeutic point of view

Each question will be chosen from among the problems of present-day science and will be discussed by lecturers whose personal research competence and recognized authority are certain guarantees of the value and importance of each session.

The reports will be printed and distributed in the form of brochures. Each brochure will contain a summary of the latest developments concerning the question studied and in all will constitute a cardiovascular library of great value to the practitioner. The unpublished documents, valuable diagnoses and therapeutic indications can be used advantageously by the physician in daily practice.

The first International Cardiological Meeting will be held at Royat during Whitsuntide 1936 (May 31 June 1). The question to be discussed is Vascular Spasm.

Professor Vaquez will preside at the meeting. Reports will be delivered by Professors O. Heymons of Ghent and Lucien Bronha of Liege. Physiological Aspect of the Vascular Tonus.

Professor Riser of Toulouse. Vascular Spasm of the Brain.

Professors Leriche and Fontaine of Strassbourg. Vascular Spasm and the Limbs.

Professors Maranon and Duque of Madrid. Relation of Vascular Spasm to Endocrinology.

Professor Loeper of Paris. Treatment of Vascular Spasm.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday April 16 in the Amphitheatre of the Peter Bent Brigham Hospital Dr. Henry A. Christian, Physician in Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12 staff rounds will be conducted by Dr. Christian.

A PHOTOGRAPH OF DR. IRA VAN GIESON WANTED

In connection with the compilation of the history of the New York Psychiatric Institute Dr. C. O. Cheney, 723 West 168th Street, New York City, would like a photograph of Dr. Van Gieson.

REPORTS AND NOTICES OF MEETINGS

NEW ENGLAND HEART ASSOCIATION

The monthly clinical meeting of the New England Heart Association was held at the Memorial Hospital, Worcester, on February 24, 1936.

The first paper of the evening was given jointly by

Dr. O. H. Stansfield and Dr. E. H. Halloran and was devoted to the early and remote effects of acute contagious diseases upon the heart. The effect of diphtheria toxin on the myocardium was taken as an extreme example. In diphtheritic myocarditis the mortality was high but if recovery occurred it was almost always complete. It is reasonable to assume however that in some apparently completely recovered cases scars are left in the myocardium which may contribute to heart failure in later life. In scarlet fever in addition to direct cardiac damage the risk of renal injury must be borne in mind as this may lead eventually to cardiovascular renal disease. Influenza may be followed by circulatory weakness which persists for months or even years. In all acute contagious diseases the possibility of cardiac involvement must be considered and violent exertion during convalescence prohibited.

Dr. Frank B. Carr reported his observations on six cases of acute benign pericarditis occurring in otherwise healthy young people without evidence of myocardial or endocardial involvement. These cases were considered to be analogous to cases of acute fibrinous pleurisy in which there is no significant involvement of the parenchyma of the lung and no pleural effusion. It was suggested that such cases frequently had escaped recognition because the onset is often that of an acute respiratory infection accompanied by the generalized muscle pains usually associated with grippe, and the pericardial friction rub may not appear until relatively late in the course of the infection.

Dr. John J. Dumphrey spoke on the subject of Angina Pectoris Complicating Pernicious Anemia. In a group of thirty-one cases of pernicious anemia seen by the author nine presented the typical anginal syndrome. Eight of them were followed over a period of from two to eight years, averaging five years. All were relieved of anginal attacks while under treatment of the anemia, but four subsequently developed acute coronary thrombosis with definite clinical and electrocardiographic evidence. It was also noted that several patients in this series developed significant rises in blood pressure as their anemia improved under treatment.

SOUTH EASTERN MASSACHUSETTS HEALTH OFFICERS ASSOCIATION

Some thirty health officials of towns from Brockton to the tip of Cape Cod met in Hyannis on Wednesday, January 29, for the regular quarterly meeting of the South Eastern Massachusetts Health Officers Association. The president called for the regular business meeting in the course of which Mr. A. J. Strawson, the recently appointed Executive Secretary of the Massachusetts Tuberculosis League, was made honorary member of the association.

The principal speaker was Dr. Mary R. Lakeman of the Cancer Division of the Massachusetts Department of Public Health who outlined the efforts of

the division toward the control of cancer on Cape Cod. In this work Dr Lakeman is visiting every town in the district, making direct contact with the officers and directors of the many local associations, women's clubs and social groups, with due attention to the organizations of men. For the past fifteen years there has been an increasing realization of the necessity of caring for chronic diseases, and success has been achieved to the extent of adding about five years to the average human life.

Since 1925 legislation has been chiefly for large hospitals to care for older persons, and in 1926 a cancer division was added to the other State Health Department activities. Dr G. H. Bigelow, the then Health Commissioner of Massachusetts, undertook the problem of proper development of the work, secured the advice of the cancer experts of the medical societies, men with wide experience, and in addition, undertook extensive local studies. One outcome was the realization of the fact that the malady often needs long care that hospitals cannot give. Boards of health were not brought into the matter at the time, but steps were taken to build up clinics, with some hospitals. There are eighteen such clinics today.

Especial reference was made by the speaker to a later work of research undertaken by Dr Bigelow and Dr Herbert L. Lombard, published in book form with the title, "Cancer and other Chronic Diseases in Massachusetts." In accord with the growing realization that education of the people is fundamental to progress, the State Department has devoted two of its recent bulletins to cancer, while the American Society for the Control of Cancer has done much toward interesting the health departments and the public in the subject.

The speaker sketched some of the problems presented by other chronic diseases, among them heart ailments, arthritis and diabetes. They all present some similarities, in that prevention is the modern resource of their elimination. Here Dr Lakeman emphasized the importance of early discovery, the means for which include periodical medical examination. In cancer approximately half of all the cases are curable if recognized in time, but in cancer of the skin, a very large percentage will yield to treatment.

A campaign for the information of the "man on the street" is now underway, and by means of local groups, as already suggested. These should include professional groups like boards of health and medical societies as well as the lay professional business and social associations. There is now an earnest endeavor to interest the latter in organizing educational meetings, at which the medical men will provide facts and information. It is hoped that centres may be established with active leaders in all the towns. Thus public education in prevention and in general health may be promoted.

Mr Bernard E. Bradley of the Cancer Division continued the general subject with facts and figures. Two difficulties of the day are delay in treatment

and refusal to recognize the symptoms. Inasmuch as physicians in Massachusetts are caring only for a small ratio of the actual cases, it is necessary to bring the matter into the open and talk about it. Since the people have begun to understand about tuberculosis, the death rate has been very materially lessened. In cancer, likewise, the responsibility is on the people. There are facilities for treatment and care, but the patient should get this treatment in early stages of the disease.

Mr Strawson voiced the greetings of the Massachusetts Tuberculosis League, and stated that clinics should be provided for promptly to the end that the plan under Dr Chadwick's supervision should be carried forward. The people must be educated to full cooperation with existing facilities including sanatoria and clinics.

The meeting then resolved itself into a "round table", with free discussion, some of the participants being Dr Richard P. MacKnight, State District Health Officer, Dr E. F. Curry of Sagamore, Dr A. P. Goff, County Health Officer, and Mr Charles R. Stowers of the Falmouth Board of Health.

Mr W. Fred Delano, health officer of Fairhaven, discussing the special subject of diphtheria, advocated the general immunization of school children, with the schools asking for information on this subject. Dr Swift, reporting for Falmouth, noted that in 1930 and 1931, the deaths from diphtheria were thirty-eight and twenty-one, respectively, and in 1932, one. In 1933, 1934 and 1935 there were none. Dr MacKnight, reporting for New Bedford, said that with a population of 110,000, the years 1934 and 1935 had no deaths from diphtheria.

HARVARD MEDICAL SOCIETY

The Harvard Medical Society met at the Peter Bent Brigham Hospital on January 28, 1936, Dr J. C. Aub presiding. The medical case was presented by Dr John Alsever. A forty-two year old housewife entered the hospital sixteen days previously complaining of tender nodules over her extremities of three days' duration. She had had five such attacks during the preceding twenty-four years, the last in 1930. The attacks always began with sore throat and diarrhea of two or three days duration, followed by the development of skin lesions over the forearms and legs, which persisted for three or four weeks, and gradually disappeared. The attacks were accompanied by malaise, and generalized joint pains. Physical examination was negative except for a red, inflamed throat, and a skin rash over the arms, thighs, and knees. The skin lesions over the arms were red and erythematous, with irregular outline and sharp border. The nodular lesions were limited to the legs, and were acutely tender. Her temperature was moderately elevated, and the white blood count varied between 12,000 and 24,000. Other laboratory studies were essentially negative. The diagnosis of erythema nodosum and erythema multiforme was made. The nodules slowly regressed,

and became less tender the joint pains subsided and the rash over the upper extremities desquamated.

Dr Fulton remarked that although the disease is spoken of as allergic it is seldom possible to demonstrate specific hypersensitivity. It was impossible to do so in this case. The patient was illustrative of the type of recurrent erythema with visceral manifestations. The same type of process observed in the skin also occurs in the internal organs with resultant varying symptoms thus signs suggestive of acute hemorrhagic nephritis or renal colic have occasionally been described.

The surgical case was presented by Dr Robert Bates. A fifty-one year old housewife entered the hospital seven days previously with the history of a lump in the right breast five years ago at which time bilateral simple mastectomy had been performed. One year ago she began to experience vague aching pains in her back and legs which had progressed in severity and which kept her confined to bed for the past six months. Physical examination showed a well nourished woman in no acute pain resting quietly in bed. There were scars of the bilateral simple mastectomy and in the right third interpace there was a hard nodule adherent to the skin and underlying tissues. There was acute pain on manipulation of the right hip and muscular atrophy of the right leg. X-ray studies showed many of the ribs and vertebrae to be involved in a widespread destructive process and there was a large area of destruction in the right ilium in the region of the hip joint.

Dr Auh commented on the marked improvement shown by some patients with metastatic carcinoma of the breast after the production of artificial menopause. Dr E. C. Cutler stated that patients past the menopause received no benefit from radiation of the ovaries.

Dr Edgar Allen, Professor of Anatomy at Yale University School of Medicine, delivered the paper of the evening speaking on "Reactions to Ovarian Hormones: Growth, Normal and Atypical in Genital Tissues."

Both ovarian and testicular hormones are essential for the growth and maintenance of the genital tissues. Recently developed synthetic preparations are able to induce development and stimulate growth processes, replacing the endocrine function of the gonads.

So great is the growth stimulus furnished by the ovarian follicular hormones that by administering relatively small dosages to ovariectomized mice and rats the vaginal wall can be replaced with new epithelium within forty-eight hours. On withdrawal of the hormone there is an enormous leucocytic infiltration of the vaginal wall and a sloughing of all but a few basal layers.

Since normal growth processes of genital tissues are so greatly accelerated by estrogenic substances it is conceivable that irregularities in the duration or mode of hormone action may result in the development of neoplastic processes. Various examples

of excessive or atypical growths induced by estrogens were then illustrated.

During pregnancy the vaginal epithelial cells of rodents are loaded with mucus and are of an appearance entirely different from that observed in epithelium under theelin stimulation. By injection of theelin in doses one-third that used to produce estrus, a picture similar to that observed in pregnancy can be produced.

Smith and Engle by implants of anterior pituitary produced an excessive number of active ovarian follicles, an increased secretion of theelin and hyperplasia of the uterus—demonstrating the anterior pituitary's influence on the ovary. The ovary also influences the pituitary. In ovariectomized animals there is an increase in the basophilic elements of the pituitary which returns to normal after injections of theelin.

Gillies theory explaining the freemartin, postulated the restraining influence exerted on the ovaries by the hormone secreted by the testes of the male twin which develop at an earlier time than the ovaries. This restraint results in the sterility of the female.

As a test of this theory injection of ovarian extracts into incubated eggs (genetic males) has produced development of Müllerian rudiments in male embryos. Injection of potent extracts into male chick embryos has caused not only a swing toward female characteristics but has caused the development of an ovarian cortex in the male gonad and example of true "sex reversal" (Willer).

Injections of theelin into monkeys cause growth of the uterus with great mitotic activity in the surface epithelium and glands. Injections of corpus luteum hormone cause rapid changes in the endometrium—the disappearance of mitotic activity and transformation of glands to the premenstrual type.

The junction between the stratified and columnar epithelium of the cervix is a point of physiological "weakness" and it is here that carcinomatous changes frequently occur in the human female. Injection of large amounts of theelin into monkeys with or without traumatizing the cervix will result in metaplasia of cervical glands—a stratified epithelium developing beneath the columnar epithelium in a fashion suggestive of malignant change (Overholser and Allen). This type of metaplasia has been prevented by injections of corpus luteum hormone (Hilaw). In women at the menopause there is cessation of ovulation and corpus luteum formation with a persistence of theelin secretion. It is possible that this endocrine unbalance may be a factor in the development of cervical neoplasms although the long latent period between the action of the stimulus and the appearance of the cervical tumor is not easily explained.

The genital swelling of the chimpanzee and the sexual skin* of the Macaca monkey can be attributed to extreme development by prolonged injections of theelin. Swelling and wrinkling of the skin of large areas of the body may be produced by extreme dosages (Bachman et al.) and histological

inspection of the subcutaneous connective tissue shows a mucoid change, similar to that observed in the cock'scomb following injections of the male sex hormone

Long continued injections of folliculin benzoate into male mice caused the development of scrotal herniae, overgrowth and distention of the bladder, hydronephrosis, and ligamentous replacement of the symphysis pubis. Similar injections into female mice resulted in death due to overgrowth of the uterus, subsequent breakdown, and fatal peritonitis. The changes observed in the symphysis pubis following these injections are of interest. There is an actual decrease in size and weight of the pelvic bones, and an active proliferation of periosteal cells. The joint cavity is obliterated and the symphysis replaced by a ligament (Gardner).

Studies of the mammary glands have shown that there is marked growth of the mammary tree as a result of theelin stimulation. In the rabbit the corpus luteum hormone is necessary for growth of the alveoli, but such growth occurs in the guinea pig under the stimulus of theelin alone.

By means of ovarian transplant in male mice of cancer susceptible strains, or with injections of a concentrated estrogenic hormone, overgrowth of the mammary rudiments of the male has been produced (Lacassagne, Gardner). Atypical growths appear in the form of multiple nodules and hyperplastic areas persist after the withdrawal of the hormonal stimulus. Some of the animals actually develop carcinoma of the mammary gland. These tumors have been transplanted in males as well as in females and continue to grow without further hormone treatment. Genetic factors for cancer are present in these mice but the males do not have mammary carcinoma because of absence of the ovarian hormone necessary for mammary development. Six animals have also developed sarcomata at the sites of injection.

Several instances of multiple tumors in physiologically related tissues have been observed. One animal with a chromophobe adenoma of the anterior lobe of the pituitary fourteen times the weight of the normal gland also had granulosa cell tumors of both ovaries, extreme hyperplasia of the uterus, and multiple (six) mammary cancers.

Dr Fuller Albright in commenting on the paper questioned whether mammary acini could be caused to develop from injection of estrin alone in pituitarectomized animals, since estrin induces the production of a corpus luteum like hormone from the pituitary, which might be responsible for the stimulation of the acinar elements. Dr Allen replied that in the guinea pig complete development of the mammary tissue may be produced by theelin alone.

Dr J C Aub emphasized the fact that so far experimental neoplasms have been produced only in highly susceptible strains of animals, and that conclusions from these experiments should not be applied as yet to general problems of neoplastic diseases. Dr Allen agreed with this view, but remarked

that sarcomata have been produced in strains of animals not susceptible to this particular tumor and that further experiments with high doses of estrogens and carcinogens looked promising.

Dr John Rock emphasized the distinction between endocrinology and organotherapy, and pointed out that experimental findings in animals must not be applied too freely to clinical fields.

Dr F L Hisaw stated that the interreaction of follicular and corpus luteum hormones was peculiar, since the simultaneous action of the two on the endometrium causes greater proliferation than is obtained by either alone. Prolonged action of estrin for a period of some twenty days at high dosage levels results in a cessation of mitotic activity which may necessitate a revision of conclusions drawn from endometrial biopsy material.

SUFFOLK DISTRICT MEDICAL SOCIETY AND THE BOSTON MEDICAL LIBRARY

JOINT MEETING

A joint meeting of the Suffolk District Medical Society and the Boston Medical Library was held at the Library on Wednesday evening, January 29. Dr Walter B Cannon, George Higginson Professor of Physiology at Harvard Medical School, was the speaker for the evening. Dr Cannon delivered a very delightful and interesting address on some of his experiences in his trip around the world. He went west via Hawaii to fulfill an engagement as visiting Professor of Physiology in Peiping, crossed Siberia to attend last summer's Physiological Congress in Leningrad, and then returned to America via Scandinavia and Scotland.

Dr Cannon mentioned the very active medical society of Honolulu, and said that this congenial group is always on the lookout for medical men visiting Hawaii, so that a meeting and speeches can be arranged. The speaker was seven weeks in China, visiting Shanghai, Nanking, and the remainder in Peiping. Everywhere there were enthusiasm, new projects, and new buildings. The great inventiveness of the Chinese was contrasted with a certain primitive simplicity which seemed at times almost pathetic. A graphic description of Peiping's dustladen streets, filled with vendors and hawkers, was given. The city boasts a first-rate Medical School, with teachers and research men trained in the best laboratories in the world. Fifty per cent of the graduates go into public service work, the greatest need in China today. The wooden houses, and cleanliness and trimness of Japanese villages, were contrasted with the mud-made villages of China, as Dr Cannon talked of his three weeks' visit to Japan.

Most of the evening, however, was devoted to an account of conditions in the Soviet Union. The complete femininity of the slightly built women of Japan was contrasted with the strong, toughened, hard-working character of the women seen on arrival in Vladivostok. Eight days' journey across Siberia in hot July was next described—flies every

where dull, drab dress small infrequently placed buildings and many prison-camps and working prison-gangs. In Russia itself, women were working in foundries and factories on the same jobs as men. Propaganda was ubiquitous and omnipresent—statues of Marx and of Lenin and Stalin, red banners of exhortation, filled the streets and squares as everyone talked of “the new life” and “the new state.” Great industrial activity has been coupled with tremendous inefficiency. Several amusing anecdotes concerning late trains, inaccuracy of hotel registers etc. were told. Ten days were spent in Moscow and one week in Leningrad. Communism in the strict literal sense of the word was found not to exist. There is variation in position and variation in remuneration and some things (e.g. a man's house and its contents) are “private property” though the land belongs to the state. Even on the collective farms the farmer can use his two acres his pig and his chickens as he pleases. There is construction everywhere, not always well done as this previously agricultural people turns toward industrialism and often the new machines are handled in the most inept manner. The high regard for the human factor in labor was most impressive. The work day is six hours long with every sixth day a day of rest. If the job is an especially hard one a five-hour day and rest day every five days are obtained. Summer camps for children and vacation resorts for working people, are found outside the large cities and “parks of culture and rest” providing all forms of entertainment, recreation, games and rest, are established in the centers of the large cities. Gifted children are selected and given special attention in their schooling and in the universities and graduate schools the student is paid according to his work and dismissed if it is not satisfactory. The whole nation is air-minded, and parachute-jumping and gliding are major sports. Among other interesting places visited were a self-supporting self-governing Criminal Commune, churches now closed and used as schools or museums, and an Abolitionism. In connection with the great scientific and industrial progress many neuroses have been encountered in medical work. Private medical practice is possible, but only after the payment of a high license fee. The visitor oscillated between his enthusiasm for the achievements attained in this great country and his revulsion at the state despotism which handles moves, and removes people without regard for individual liberty right, and freedom. It is certainly true that fear exists widely though the socialist idea is winning inside the country and among the youth of the state.

Time did not permit Dr. Cannon to recount more of his fascinating observations and the meeting was adjourned shortly after ten o'clock.

BOSTON SOCIETY OF BIOLOGISTS

The January meeting of the Boston Society of Biologists was held on the fifteenth of the Chill

dren's Hospital. Dr. Robert S. Harris presented the first paper on the subject of “The Role of Chlorophyll in Hemoglobin Regeneration in Experimental Anemia.” Hemoglobin, cytochrome, and chlorophyll all have a similar chemical structure, the element magnesium holding the same central position in chlorophyll as iron does in hemoglobin. Experimental anemia was produced in white rats by feeding a special diet and then unpurified chlorophyll and chlorophyll derivatives were mixed with the diet and the hemoglobin regeneration effect studied. Of the several crude compounds used the best effect was secured by feeding iron phaeophytin. It was also found that all of the compounds had a greater regenerative power when fed with iron salt, and that the total effect was greater than the sum of the effects of the iron and chlorophyll compound alone. Highly purified potassium chlorophyllin, when fed in 20-30 milligram doses daily had a marked effect. Small traces of copper (about 7 parts per million) were present in this preparation but no iron. Phytol chloride and rhodol all derived from the chlorophyll molecule and carotene usually absorbed on to chlorophyll had no effect. Doctor Harris felt that these findings indicate that at least half of the regenerative power of chlorophyll preparations reported in the literature is due to metal impurities. Although heme pigment augments the effect of iron in the human being as does also chlorophyll, in the rat this pigment had no effect.

Dr. H. Sulkowitch with Dr. Fuller Albright spoke on “Factors Influencing the Determination of Pituitary Gonotrophic Substances in the Urine.” The prolactin of castrate urine and that of pregnancy urine are probably not identical. It was found in routine determinations of prolactin that the more old preparations were often negative. A study was therefore undertaken to determine the effect of varying pH values on the amount of prolactin found. At the lower values for pH much less prolactin was found. An excess of ammonium hydroxide could be used without harm but sodium hydroxide tended to destroy the hormone. It was also discovered that prolactin is very stable and may be stored for long periods of time without loss of potency.

Dr. George B. Wislocki spoke on “The Anatomy of the Pituitary Body of Whales—work in progress jointly with Dr. E. M. K. Gerling. In whales the neural portion of the gland is entirely separate anatomically from the anterior lobe and lies in an independent pocket of dura. Although the neural portion appears to be made up solely of glial-like tissue extracts from it producedpressor and oxytocic effects. Intermedin can be isolated from the anterior lobe, but no intermediate tissue can be seen microscopically. The whale's pituitary lies in a cushion of dural tissue which is very vascular and is essentially composed of arterial and venous retia. The pia-arachnoid much more massive than in most mammals partially surrounds the neural lobe but not the anterior lobe. The absence of any

rhythmic play of muscle forces between loss and recovery of equilibrium"

Chapter V deals with the physical properties of bone and Chapter VI with the dynamics of muscle action

In Chapter VII, the "Pathomechanics" of muscle are discussed and their practical application to the types of contractures characteristic of the different types of muscle structure and insertion. It is possible with this knowledge to discover the "key" contracture about a joint which must be first overcome if the given deformity is to be corrected.

An electrophysical analysis of normal and pathological muscle action is given in Chapter VIII. The action currents and types of motion in normal muscles are compared with those in anterior poliomyelitis, progressive muscular dystrophy, cerebral palsy, epilepsy and in muscles about ankylosed joints.

In Chapter IX, the coordination of skeletal muscle action is discussed. Mass resistance and external resistance are considered in relation to uniaxial, biaxial and pluriaxial muscles. Illustrations are given of the interesting phenomenon of a given muscle functioning at one stage of its range of motion as a flexor and at another stage as an extensor.

Chapter X is entitled "Fatigue and Recovery." The treatment and prevention of fatigue and the technique of exercise are described. The influence of the endocrine glands, of atmospheric pressure in high altitudes and of intra-abdominal pressure with resultant shallow respiration and stagnation of the blood in the abdominal veins are discussed as examples of the pathomechanics of fatigue.

Part II, the Special Mechanics of Locomotion, begins with Chapter XI, which will be of special interest to orthopaedic surgeons, indeed a small treasure house of knowledge. In this chapter consideration is given to the functional anatomy of the spine, to its external landmarks and to general postural laws. The statics of the spine from the point of view of its internal architecture, its articulations and its shock absorbing discs are elucidated.

Chapter XII continues with a description of the dynamics of the spine both as to the distribution of motion and muscle action. This is an extremely valuable contribution to our knowledge of the details of both individual and combined action of the spinal muscles.

There follow Chapter XIII on the pathomechanics of the spine dealing chiefly with anatomic variations, and Chapter XIV, into which is crowded the mechanics of the pelvis, including morphology, orientation, statics and pathomechanics.

Chapter XV deals with the mechanics of respiration and with the anatomy, physiology of the thorax, and with its pathomechanics and the paralytic disturbances of the breathing mechanism.

In Chapter XVI, the abdominal cavity is considered under headings of (1) Morphology, (2) Strains and stresses in the abdominal cavity, (3) Muscle mechanics of the abdominal wall, (4) Support of the

intra-abdominal organs, and (5) Abdominal respiration.

In Chapter XVII, the mechanics of posture are discussed. Normal posture (in geometrical terms) according to Steindler "means compensation of the spinal deflection within the spine itself, mal posture means that a deflection of the spinal column in relation to the line of gravity is compensated by the body as a whole by means of abnormal positions of the pelvis and hips and knees." This quotation may serve to illustrate the meticulousness of Steindler's anatomical and physiological descriptions. He quotes Goldthwait extensively in relation to the importance of recognizing the common types of body build and emphasizes as well the part which changes in the intervertebral discs play in youth and old age in the determination of postural deformities.

Steindler is quite "at home" in Chapter XVIII, the title of which is "The Pathomechanics of Scoliosis." He propounds his rational theory of the functional value of compensatory curves and pleads for a much earlier recognition than is now generally afforded of the prescoliotic stage.

The next eight chapters, XIX to XXVII, take up in most full and helpful manner the individual mechanics of the main articulations, namely, those of the hip, knee, ankle and foot, the lower extremities as a whole, the shoulder, elbow, wrist and fingers, and the arm as a whole. Chapters XXVIII and XXIX offer respective considerations of "The Mechanics of the Human Gait," "Graphic Description of the Gait," and "Pathomechanics of Gait."

The concluding Chapter XXX is entitled, "Rationalization of Work in Locomotion." By rationalization is meant "the adaptation of motion to the individual work in such a manner as to produce the highest possible quotient of efficiency."

"The Mechanics of Normal and Pathological Locomotion in Man" should not be read hastily, indeed, cannot be read hastily with any profit. It is "heavy going" but the weightiness of the subject justifies the reader in proceeding slowly. If one does proceed thus slowly he will be likely to arrive at the same conclusions as the thoughtful and erudite Professor Steindler. The book is well written, well illustrated and well indexed. It is an excellent piece of bookmaking.

National Medical Monographs. Industrial Medicine.
W. Irving Clark and Philip Drinker. 262 pp. New York: National Medical Book Company.

This book fills a long felt need. It describes clearly and succinctly the objectives to be attained by industrial medical service, clearly defines the functions of the industrial physician, the methods and means by which medical services in industry may achieve the optimum of practical utility. The sections on physical examinations, industrial surgical service and pneumoconiosis are excellent. The book may be read and studied with profit by all whose medical practice brings them in contact with workers.

PROGRESS IN THE RECOGNITION OF CONGENITAL HEART DISEASE*

BY SYLVESTER MCGINN, M.D.† AND PAUL D. WHITE, M.D.†

OUR knowledge of cardiovascular disease has increased in all directions during the past decade. The study of congenital heart disease has shared in this progress and has become of great importance as well as of great interest. Although abnormalities of the heart present at birth have been known to exist for centuries, contributions on the subject have largely been confined to postmortem observations. It is in recent years only during which time we have been aided by the fluoroscope and electrocardiograph, that we have been able to make the diagnosis clinically with any degree of confidence. The time has now arrived when it is not sufficient to make the broad diagnosis of congenital heart disease without having definite structural defects in mind.

We have recently reviewed 7500 autopsy records at the Massachusetts General Hospital to determine the frequency with which congenital heart disease has been occurring there since 1895. In addition we have more closely analyzed the cases coming to autopsy in the last fifteen years to judge the accuracy of our relatively recent clinical diagnoses of congenital heart disease.

1. Incidence of Congenital Heart Disease in the Postmortem Examinations of the Massachusetts General Hospital

In 7500 postmortem examinations performed in the last forty years, congenital heart disease was found sixty seven times, representing an incidence of 0.9 per cent. Only definite cases of congenital defects were included thereby eliminating a large group of cases with foramina ovales functionally closed but patent to the passage of a probe. About one third (twenty one) of the sixty seven patients were infants under one year of age.

Thirty four hundred of the 7500 autopsies were made in the last fifteen years, and the clinical records of the forty-one cases having congenital lesions of the heart present among these autopsies were subjected to further study. The incidence of congenital heart disease in the latter group was 1.2 per cent whereas only

half as many, or 0.6 per cent, were observed in the preceding 4100 cases. This suggests that more congenital defects can be found with more careful examination of the heart.

Lesions permitting a flow of blood between the arterial and venous systems were found in twenty hearts (about half). The most common congenital defect of all in the 3400 autopsies of the last fifteen years was patency of the ductus arteriosus which occurred alone in four cases and in combination in five others. An interauricular septal defect occurred alone in one case, and in combination in six others. These two lesions were associated five times. One of the hearts with a patent ductus arteriosus also had coarctation of the aorta. One of the cases with imperfect closure of the auricular septum had mitral stenosis in addition a combination known as Lutembacher's disease.

Four hearts had interventricular septal defects, and two others were complicated by pulmonary stenosis. Dextroposition of the aorta and enlarged right ventricle comprising the tetralogy of Fallot. In one heart there were defects in both the auricular and ventricular septa. One three chambered heart was found a cor triatriatum trilobulare, and there was one two-chambered heart, a cor bilobulare. Three cases of congenital idiopathic hypertrophy were described. Abnormalities of the coronary vessels were noted in five cases.

Abnormalities in the heart valves accounted for thirteen of the forty-one cases. Bicuspid aortic valves were noted in seven hearts, a bicuspid pulmonary valve in one pulmonary valve with four cusps in two and pulmonary stenosis, single mitral leaflet, and variation in the size of the aortic cusps in one case each.

In contrast to this group of forty-one cases observed during the years 1921 to 1935 inclusive, congenital defects were discovered in twenty six patients between 1896 and 1920 during which time 4100 postmortem examinations were performed. In eight hearts uncomplicated defects in the interauricular septum were present. Uncomplicated patent ductus arteriosus and interventricular septal defect were found once each. Pulmonary stenosis was associated with an interauricular septal defect in two cases and with an interventricular septal defect once. In eight cases there were patencies in both the interauricular septum and the duct.

tus arteriosus In one heart there was an interauricular septal defect associated with mitral stenosis A bicuspid aortic valve was found three times, and in one case it was noted that the pulmonary valve had four cusps

The apparent discrepancy in the incidence of congenital lesions in these two groups seems to rest upon the observations of the coronary vessels and of the heart valves The number of defects allowing admixture of blood were about equal in the two groups The coronary vessels have been inspected much more carefully by the pathologists in recent years Evidence of this is illustrated by the five cases of abnormal coronary arteries observed in the last fifteen years, in contrast to the failure to note any prior to that time The relative incidence of congenital defects of the valves in the earlier and later groups were four and thirteen respectively

B Accuracy of the Clinical Diagnosis of Congenital Heart Disease

The clinical records of the forty-one cases examined postmortem in the last fifteen years were analyzed to estimate the accuracy of our diagnoses A correct diagnosis was made seven times and included four adults and three infants under one year of age The cases in this group consisted of three with idiopathic congenital hypertrophy, two with interventricular septal defect (one of these had also a patent foramen ovale), one with the tetralogy of Fallot, and one with pulmonary stenosis

In five other cases, including one infant the correct diagnosis was suspected and so entered on the record This group comprised three cases with an interventricular septal defect, one with an interauricular septal defect, and one with a patent ductus arteriosus These twelve cases in which a correct diagnosis was made or very definitely suspected represent 29 per cent of the congenital lesions coming to autopsy in the last fifteen years and include four of the eleven infants, or 36 per cent of those under one year of age The correct diagnosis of congenital cardiovascular defects is, however, very difficult in infants under six months of age, as has been indicated by studies at the Children's Hospital in Boston

In three cases a diagnosis of congenital heart disease was made, but the anatomical defect was not noted One of these cases had a cor biloculare The two others showed congenital hypertrophy diagnosed as idiopathic, but one had an abnormal coronary supply and the other had a patent ductus arteriosus

One case was diagnosed wrongly as to the congenital structural defect in the heart, viz, a case of tetralogy of Fallot which was believed to have a patent ductus arteriosus

In the remaining twenty-five cases, including four infants, the diagnosis of congenital heart

disease was entirely unsuspected Thirteen of these hearts had defects in the structure of one of the valves, seven of them having bicuspid aortic valves There were four cases with abnormal variations in the coronary vessels There were two cases of patent ductus arteriosus alone and five in which it was associated with an interauricular septal defect Finally, a case of cor biloculare was thought to have rheumatic heart disease

Of the twenty-three cases of idiopathic hypertrophy or of congenital defects allowing admixture of blood, the correct diagnosis of specific structural defects was made or suggested in eleven (48 per cent)

The correct diagnosis was not made or suggested in any of the twenty-six cases of congenital heart disease found in the first 4100 postmortem examinations In two cases the presence of congenital heart disease was suspected, but the specific lesion was not suggested. One of these cases had an interauricular septal defect associated with mitral stenosis, and the other case was one of pulmonary stenosis with septal defects

A third group of cases was analyzed for comparative purposes and included all of the cases of congenital heart disease proved at autopsy that had been previously examined by members of the staff of the cardiac clinic in or outside the hospital A majority of these was included in the 7500 autopsies reviewed A correct diagnosis was made or suggested in eleven of the nineteen cases (58 per cent) it was made in two cases of the tetralogy of Fallot, two cases with interventricular septal defects, one case of patent ductus arteriosus, one case of idiopathic hypertrophy, and one case of pulmonary stenosis, and was suggested in three cases of interventricular septal defect and in one case of interauricular septal defect. The correct structural diagnosis was unsuspected in six cases (although in one of these a finding of congenital heart disease was made) three with bicuspid aortic valves, one with a pulmonary bicuspid valve, one with a single mitral leaflet, and one with an anomalous coronary vessel If these six cases, which gave no characteristic clinical signs, are eliminated, the correct diagnosis was made or suggested in 85 per cent of this small group of cases

DISCUSSION

In reviewing our series of cases with the aim of improving our diagnostic ability, we are confronted with a large group of lesions, namely, those of defective valve structure and abnormal coronary vessels, which at the present time provide no evidence to suggest their presence There is some importance in recognizing abnormalities of the valves, not that they always interfere seriously with the cardiac function but because they so frequently are the

foci for subacute bacterial endocarditis. The bicuspid aortic valve is the most common and most important of the group, and so far as we know has no clinical manifestation. Other valvular defects such as pulmonary valves with four cusps, bicuspid pulmonary valves and mitral valves with a single leaflet give no clinical evidence of which we are aware. As yet we are unable to recognize, with one possible exception to be noted below, hearts supplied by a single or anomalous coronary vessel. Further observation of this rather large number of cases with silent congenital lesions is necessary before we can improve much further our accuracy in diagnosing congenital heart disease.

Within recent years congenital cardiac lesions have provided sufficient evidence of some defects and suggestive evidence of other defects to permit us to make the diagnosis with certainty or at least to suspect that it is present. More experience will eventually allow us to be more confident. The x ray and electrocardiograph have been very helpful in obtaining further clinical evidence.

We believe that it will prove helpful to present herewith the diagnostic clues to some of the individual and combined defects of congenital heart disease with which we have recently become more familiar as well as to the very few defects that have been clinically recognized for many years. We shall begin with the latter.

1 *Patent ductus arteriosus* The ductus arteriosus which connects the pulmonary artery and aorta in the fetus normally atrophies two or three months after birth and is later represented by a fibrous ligament. The failure of this vessel to close, results in a permanent shunt between the greater and lesser circulations. Such a shunt is often associated with other anomalies and not infrequently has a compensatory function.

The most characteristic clinical sign of this condition is a typical murmur. It is heard best, and sometimes only in the second left inter space and is a harsh humming murmur with a sound similar to a mill wheel or the machine-like purr of a large motor. It is continuous with accentuation during systole and may be accompanied by a thrill.

Cyanosis and clubbing of the fingers are usually absent. Cardiac enlargement, especially involving the right ventricle may be present and consequently may produce right axis deviation in the electrocardiogram. X ray examination is usually characteristic and sometimes pathognomonic with a variable degree of prominence in the region of the pulmonary conus. Fluoroscopic may show a pulsation of the lung hilus shadows.

2 *Interventricular septal defects* A defect in the interventricular septum (Roger's disease

1879) is one of the most common congenital lesions to be recognized clinically. The defect is usually a patency in the interventricular septum, one or two centimeters in diameter situated just below the aortic valve and allowing a free passage of blood between the two ventricles. Other malformations of the heart frequently complicate this condition.

Cyanosis is a rare finding in the uncomplicated cases. The left ventricle is stronger than the right, so that the tendency is for the oxygenated arterial blood to be shunted through the opening to the venous side of the circulation. This condition persists until the left ventricle fails.

There are several findings which may lead one to make the correct clinical diagnosis. The most important evidence is the presence of a harsh systolic murmur heard best at the third left inter space and more or less confined to that intermediate area but frequently heard in the back between the scapulae. There is usually a thrill accompanying the murmur. Any intense murmur heard in infancy justifies the assumption that it is due to a lesion present since birth, and defects of the interventricular septum are among the most common congenital lesions detected clinically. This information may have to be obtained from the obstetrician if the patient is beyond infancy. X ray examination fails to show gross enlargement despite the loud murmur. There is an unusual blunting of the apex, probably due to the changes in the right ventricle, but it is not a pathognomonic finding.

3 The term *idiopathic congenital hypertrophy of the heart* refers to enlarged and dilated hearts observed at birth or early infancy and for which no cause can be discovered.

4 *The tetralogy of Fallot* is a fairly common congenital lesion that we can now recognize. It consists of (a) stenosis or narrowing of the opening of the pulmonary artery at the valve cusps or of the infundibulum just below it (comparable to the fibrous ridge found in sub-aortic stenosis), (b) an interventricular septal defect, (c) dextroposition of the aorta which means that the aortic opening is moved farther to the right than is normal and overlies the septal opening and (d) hypertrophy of the right ventricle.

The course of the blood flow in the heart is as follows: the venae cavae empty into the right auricle from which the blood flows into the right ventricle. At this point the flow of blood obstructed by the narrow pulmonary orifice only in part enters the pulmonary artery, the balance going directly into the aortic orifice which rides over the interventricular septal defect and so receives blood from both ventricles. The right ventricle hypertrophies to accommodate itself to this increased work and the aorta is larger than normal. Cyanosis results from

the large quantity of unaerated blood being shunted into the arterial circulation. The cyanosis is usually intense but occasionally it does not become apparent, except in paroxysms until later life. The lungs receive less blood than normally and pass it on to the left auricle and left ventricle which may be somewhat small. Thence the oxygenated blood enters the aorta along with the unoxygenated blood from the right ventricle.

There are five findings, which when they occur in association permit the diagnosis of the tetralogy of Fallot with a high degree of certainty. First, there is usually cyanosis of lips, cheeks, ears, fingers, and toes, secondly there is clubbing of the fingers and toes, thirdly, a loud systolic murmur is heard best in the pulmonary valve area and in the third left interspace (at times accompanied by a systolic thrill), fourthly, there is marked right axis deviation by electrocardiogram in as extreme a degree as we ever see, and fifthly, x-ray examination shows the heart to be sabot-shaped due to enlargement of the right ventricle without enlargement of the pulmonary artery. (The great vessels will be prominent on the right due to the dextroposition of the aorta but not to the left because of the small amount of blood passing through the hypoplastic pulmonary artery.)

The prognosis may be good, for we have seen instances of a noted musician who died in his sixtieth year, the diagnosis proved by necropsy, and of a woman now sixty-two years old who works as a librarian without complaints other than that of cyanosis. The average age at death in eighty-five cases was twelve and one-half years (Abbott).

There are five other congenital lesions found in our postmortem series that have clinical evidence sufficient to allow one to suspect the diagnosis. As time will give us further opportunity to study similar cases, we may make these diagnoses with confidence comparable to that which we feel in the more common lesions.

5 *Coarctation of the aorta*, or narrowing of the lumen of the aorta, is a congenital anomaly with which we have become familiar in recent years and which we can now diagnose clinically with ease if it is at all pronounced. The narrowing of the aorta most frequently occurs at the point where the ductus arteriosus joins it. The ductus normally disappears leaving a fibrous ligament in its place. It is believed that this fibrous or atrophic change involves the walls of the aorta and narrows its lumen. This materially interferes with the circulation beyond the point of narrowing, diminishing the volume of blood going to the lower extremities and necessitating a collateral circulation. The internal mammary and intercostal arteries become much larger than normal and by a circuitous route supply blood to the lower parts of

the body and thus comprise the chief factors in the collateral circulation.

There are five points that make the clinical diagnosis possible. (1) Hypertension occurring in children and young adults should make one suspicious of aortic coarctation and should direct the search along that line. (2) The blood pressure is higher in the arms than it is in the lower extremities and the dorsalis pedis, tibial, and popliteal pulsations may be absent. Normally the blood pressure in the legs is considerably higher than in the arms. (3) The blood vessels of the trunk, especially the intercostal and mammary arteries, can be seen and palpated as they pulsate vigorously. (4) A harsh systolic murmur can often be heard at the base of the heart and in the back. (5) X-ray examination may show evidence of left ventricular hypertrophy and especially of notches in the ribs made by the dilated intercostal arteries. The x-ray finding of rib notching is pathognomonic.

The prognosis in these cases is varied, the oldest subject on record being ninety-two years of age. Ultimately the patients may die of cardiac failure, rupture of the aorta, or subacute bacterial endocarditis to which they are especially susceptible.

6 *The persistence of a right aortic arch* is another congenital anomaly with which we have become familiar in the past few years. There are several variations of this condition, but in brief the aorta starts from the left ventricle in its usual position, ascends to the right of the sternum, but at the arch it courses to the right rather than to the left and then finally swings behind the esophagus and trachea to the left of the spine where it descends through the thorax into the abdomen. Both the esophagus and trachea are subjected to the pressure of the transverse aortic arch behind and to the remnant of the ductus arteriosus (the ligamentum arteriosum) on the left side. The ligament runs from the aorta to the pulmonary artery and completes an encircling and constricting collar around the trachea and esophagus.

The presence of symptoms depends on the degree of constriction. Although most patients have no complaints and the anomaly is picked up in a routine examination, occasionally it causes dysphagia, esophageal ulcerations, respiratory distress, and even asphyxia by compression. We have recently observed a patient thought to have carcinoma of the esophagus and another who was considered to be a neurasthenic individual with globus hystericus, both of whom had this abnormality. The diagnosis can be easily made by x-ray examination with barium in the esophagus. Three findings will be observed by x-ray examination, in the anteroposterior view the ascending aorta and the aortic knob will be found to the right of the sternum, the barium filled esophagus will be displaced to the left, and in the oblique view the esophagus

gus will be pushed forward. A surgical procedure has been suggested to section the ligamentum arteriosum but we do not know of its having been done as yet.

7 *Coronary artery anomalies* In one of our autopsy cases we encountered a large heart in an infant dying at the age of three months. The clinical diagnosis was idiopathic congenital hypertrophy which proved to be incorrect when at autopsy, a single coronary artery was found arising from the pulmonary artery. The myocardium was in this case being supplied with venous rather than oxygenated blood. This nutritional disturbance and relative anoxemia of the heart muscle was reflected clinically by attacks of distress on effort like nursing (probably angina pectoris) and in the electrocardiogram by inverted T waves of the coronary type and analogous to those found when there is anoxemia of the heart muscle as the result of coronary occlusion and myocardial infarction. In the future when confronted with the findings of congenital hypertrophy and inversion of the T wave we shall consider this diagnosis as probable.

8 *A cor biatritum trilobulare* or a three chambered heart with two auricles and a single ventricle, was found once in our autopsy series. It was wrongly diagnosed as rheumatic heart disease with pericardial effusion. In the future a heart with a "water bottle" shape similar to the x ray picture of this case associated with the conduction disturbance of intraventricular block in the electrocardiogram, will make us suspicious of a cor trilobulare.

9 Defects in the septum separating the two auricles, or *interauricular septal defects* are among the commonest of congenital cardiac lesions found at postmortem examinations. The foramen ovale so important in the fetal circulation does not become entirely closed until the eighth month after birth. It has been estimated that in 25 per cent of the hearts seen at postmortem examination the foramen ovale is open sufficiently to allow passage of a probe. However this type is unimportant and we refer to an actual aperture of a centimeter or more when we speak of an interauricular septal defect.

(a) Although interauricular septal defects are not uncommon at necropsy the diagnosis is rarely made clinically largely due to the fact that they are symptomless unless the lesion is of extreme degree. There are four findings to suggest this anomaly. First late cyanosis (cyanosis tardive), usually intense occurs with severe illness or at approaching death and may be due to an interauricular septal defect. What ever exchange of blood ordinarily takes place is from the left to the right auricle. When the right ventricle fails, a reversal of flow follows

with a consequent cyanosis due to increased right auricular pressure. Secondly, the x ray of the heart shows a large pulmonary artery enlarged hilar shadows and an enlarged right ventricle. The pulmonary artery or one of its main branches may become so dilated that it is mistaken for a pulmonary aneurysm. Thirdly, the electrocardiogram shows right axis deviation. Fourthly there may be "paradoxical embolism" a condition characterized by the passage of emboli from the systemic veins or right auricle into the systemic arterial circuit through an auricular septal defect. There are no murmurs to be heard with the stethoscope.

By the time there is sufficient evidence to make a clinical diagnosis, the heart has undergone extensive changes and the prognosis is poor.

(b) *Interauricular septal defects in association with mitral stenosis* are rarely found there being only twenty four reported in the literature, two of which were noted at the Massachusetts General Hospital. It is worth while to discuss the condition because it illustrates so well alterations in blood flow. Because of stenosis of the mitral valve the pressure of blood in the left auricle rises. A considerable portion of blood passes through the interauricular septal defect rather than through the slit like mitral valve. This blood passes from the right auricle into the right ventricle and thence to the lungs for a second time. As a consequence of doing double duty, the right ventricle hypertrophies and the pulmonary artery dilates. The aorta on the other hand remains small and aplastic because it is receiving but a small amount of blood.

X ray study is the most important aid in making the diagnosis clinically and it shows the changes mentioned above namely a large heart due to an hypertrophied right ventricle a dilated pulmonary conus an enlarged right auricle and a small aplastic aorta. The hilar shadows are also enlarged to such an extent that they have been mistaken for the mediastinal glands of Hodgkin's disease and unsuccessfully given x ray therapy. The electrocardiogram shows right axis deviation.

It is evident that cyanosis is at first unlikely in this condition since the blood is actually being aerated in the lungs twice. Eventually however the right ventricle may fail and blood then backs up into the right auricle increasing the pressure within that chamber. A reversal of flow then takes place with venous blood pouring through the interauricular septal defect into the left heart chambers and systemic arteries to cause cyanosis. Finally the venous pressure is increased as is indicated by dilated neck veins and an engorged tender pulsating liver. An enlarged heart is easily detected on physical examination and a mitral diastolic murmur can be heard.

SUMMARY

A review has been made of 7500 postmortem examinations and their clinical records at the Massachusetts General Hospital to determine the incidence of congenital heart disease and the accuracy of diagnosis before death. Congenital defects were found in sixty-seven hearts or 0.9 per cent, of which twenty-one were infants under one year of age. The correct diagnosis was not made or suggested in any of the twenty-six cases found in the first 4100 (seen before fifteen years ago). In the last fifteen years forty-one hearts with congenital lesions were found in 3400 autopsies and the correct diagnosis was made or suggested in 29 per cent and for the group of infants under one year of age in 36 per cent. The members of the cardiac clinic staff examined nineteen cases of congenital heart disease that subsequently came to autopsy

and made or suggested the correct diagnosis in 58 per cent. Abnormalities of the heart valves and anomalous coronary arteries comprised a large portion of the cases and undoubtedly prevented a higher percentage of accuracy in clinical diagnoses because of the failure of these lesions to give clinical signs. If these lesions were omitted, the correct diagnosis was made or suggested in 48 per cent and 85 per cent respectively of the two series of cases analyzed.

We have presented clues to the diagnosis of the more important congenital cardiovascular defects: (1) patent ductus arteriosus, (2) interventricular septal defects, (3) idiopathic congenital hypertrophy of the heart, (4) the tetralogy of Fallot, (5) coarctation of the aorta, (6) the persistence of a right aortic arch, (7) coronary artery anomalies, (8) cor batriatum triloculare, and (9) interauricular septal defects, with and without mitral stenosis.

CLASSIFICATION OF CONGENITAL HEART LESIONS NOTED AS FOUND IN 7500 AUTOPSIES
AT THE MASSACHUSETTS GENERAL HOSPITAL

	Autopsies 1 to 4100	Autopsies 4100 to 7500	Total

THE INCREASE IN CORONARY DISEASE AND ITS CAUSE

BY FRANCIS P. DENNY, M.D.*

THERE is frequent reference in the literature to the increase in mortality from disease of the coronary arteries. It is probably the impression of most physicians who have been in practice for the past twenty years that more of their patients are now dying of coronary disease than formerly.

Statistical evidence of this increase except during the past five years is very meagre because the International Classification of Deaths, until its 1930 revision, had no subdivision for diseases of the coronary artery and this important group was included under "Other diseases of the heart" (No. 90 of the 1920 Classification) which included every form of heart disease except acute endocarditis, acute myocarditis and angina pectoris. This was an impossible grouping from the etiological standpoint. It is therefore only since 1930 that it has been possible to determine how many deaths from disease of the coronary artery there have been in the registration area of the United States in the states, or in the various municipalities.

With the object of making available some figures on the number of deaths from diseases of the coronary artery previous to 1930 the writer has reclassified according to the 1930 International Classification the causes of all the deaths from heart disease occurring in Brookline, Massachusetts, since 1900. The causes of death are those given on the death certificates by the attending physicians or the medical examiners—the latter signing many of the certificates when death was sudden. The figures obtained are of course no more accurate than the physicians' diagnoses.

Brookline had a population of 19,935 in 1900 and this increased to 50,319 in 1935. Women predominate in those over forty-five; the ratio was sixty-one to thirty-nine in 1930. The population shows some ageing. The United States Census Report for 1900 does not give the population of Brookline by age; but in 1910 the Report showed 25.5 per cent of the population over forty-five, in 1920, 30.9 per cent, in 1930, 33.4 per cent. This amount of ageing is not sufficient to explain either the increase of over 100 per cent in the total death rate from all forms of heart disease during this period or the very great increase in coronary disease which this study disclosed.

RESULTS OF THE STUDY

The deaths from heart disease have been divided into five groups as follows:

- 1 Endocarditis, acute and chronic (91 and 92)
- 2 Myocarditis, all forms (93)
- 3 Other diseases of heart (95)
- 4 Angina pectoris (94a)
- 5 Disease of Coronary Artery (94b)

The rates of each of these groups per 100,000 population in five-year periods were obtained and are to be found in table 1. The figures

TABLE 1

DEATHS FROM HEART DISEASE IN BROOKLINE 1900-1935

Rates per 100,000 for the Different Forms
and for All Forms

Period of Years	Endo- car- ditis	Myo- car- ditis	Other dis- eases	Angi- na Pec- toris	Coro- nary Dis- ease	All Forms
	91-92	93	95	94a	94b	
1900-1904	51.1	24.1	62.3	16.7	0	154.2
05-09	93.5	33.8	47.1	1.8	3.9	201.3
10-14	97.1	56.0	47.1	24.5	4.1	228.9
15-19	67.6	89.5	23.8	28.2	9.9	219.0
20-24	66.6	115.1	28.9	27.3	13.7	251.7
25-29	55.4	127.4	36.4	36.4	39.9	296.7
30-34	46.3	117.1	26.6	22.9	94.6	307.4
1935	33.8	93.1	31.7	21.8	156.6	327.0

for 1935 have also been added. These rates are also given in the accompanying chart frequently reference to which and familiarity with the numbers used in the International Classification will make clearer the explanation in the text that follows.

All Forms. For all forms combined the chart shows a progressive increase from a rate of 153.3 per hundred thousand in 1900-1904 to 327 in 1935 except for a slight decline in 1915-1919 which was probably caused by the influenza epidemic, many heart cases having been carried off by that disease.

Endocarditis. In the chart all forms of endocarditis, acute (91) and chronic (92) including all forms of valvular disease are grouped together. There was an increase for the first fifteen years and since then a very definite decline. This decline appears in all the recent statistical reports and is probably a real one.

Myocarditis. The diagnosis Myocarditis appears to be used by physicians for those cases where, in the absence of valvular disease the

The writer is indebted to Miss Ruth Coughlin and the P. E. R. A. for much valuable assistance in this work during 1934.

prominent symptom is the failure of the heart muscle. From the point of etiology, therefore, the cases included in this group are of a number of different types. The most important is doubtless that of hypertensive heart disease, where, according to White¹, the heart muscle shows no inflammatory or degenerative changes and hence should not be diagnosed as myocarditis but as "hypertensive heart disease" (95).

Next in frequency to hypertensive heart disease there is included under the heading "Myocarditis" a group of cases where the heart muscle weakens as a result of areas of fibrosis caused by narrowing or occlusion of the cor-

CHART

Different Forms of Heart Disease 1900-1935

Endocarditis (91) Myocarditis (92) Other Diseases (93)
Angina Pectoris (94a) Diseases of the Coronary Artery (94b)

The dotted line indicates the rates for all other forms of heart disease combined if the 1935 rate for coronary disease and angina had prevailed since 1900

onary branches supplying these areas. Thus there are many cases diagnosed as myocarditis where the primary cause is disease of the coronary arteries. We need to bear this in mind when we are estimating the frequency of coronary disease.

The chart shows that myocarditis (92) increased from a rate of 24.1 in 1900-1904 to 127.4 in 1925-1929, since when there has been a slight decline.

Other Diseases (95) Under this heading are included among others "Cardiorenal disease," "Arteriosclerotic heart disease," and

"Cardiovascular disease." The latter is a non-committal term often used by medical examiners in cases where persons are found dead in their beds or in other cases of sudden death. Certainly the great majority of these sudden deaths are due to coronary disease. The term "arteriosclerotic heart disease" is an unfortunate one, because it is used for two different forms of heart disease. 1. It is used where there is a generalized arteriosclerosis with renal involvement and hypertension, 2. it is used for arteriosclerosis of the coronary arteries. We must remember then that included in "other diseases" (95) are many cases of coronary disease.

Angina Pectoris (94a) The rate for deaths certified as angina pectoris has remained fairly constant during the whole period. It was evident that in the earlier years many cases that would now be diagnosed as coronary thrombosis (94b) were called angina (94a). Thus it was repeatedly found that in cases certified as angina the duration was put down as from a few hours to several days—certainly very typical of coronary thrombosis. Furthermore it was noticeable that when a given physician had once used the term "coronary thrombosis" the diagnosis of "angina" seldom or never again appeared on his certificates.

Apparently the diagnosis "angina" is now used chiefly for those cases where there is a history of previous attacks and death is almost instantaneous. According to White², disease of the coronary artery is present in 95 per cent of cases of angina. It is obvious that angina and diseases of the coronary artery should be considered together in any etiological study.

Disease of the Coronary Arteries (94b) It was realized before this study was undertaken that the rates for coronary disease would be profoundly influenced by the fact that only during recent years have physicians recognized coronary thrombosis ante mortem. Herrick's³ epoch-making paper in 1912 first brought to the attention of the physicians in this country the clinical picture of the disease which is so frequently recognized now, but this knowledge spread slowly to the general practitioners, so that only during the past ten years have any considerable number of physicians been making the diagnosis of coronary thrombosis and their number is still increasing.

In the period 1900-1904 the word coronary does not appear on a single death certificate. In the four periods from 1905 to 1924 the rate for coronary disease increased from 3.9 to 13.9 but jumped to 39.9 in 1925-1929. From 1930 to 1936 the increase has been very rapid, the rates for these six years being 58.7, 76.6, 94.1, 101.2, 140.0, and in 1935, 156.6.

The high incidence of coronary disease in the Jewish race was obvious. Thus during 1934

and 1935 of all men dying from this cause 18.8 per cent were born in Russia, almost all of whom were probably Jews. Among men dying of all other forms of heart disease except endocarditis only 1.4 per cent were born in Russia.

The study also showed the high incidence of coronary disease among business and professional men. Thus of 489 men dying of coronary disease and angina 67 per cent were of the business and professional class, while of 704 men dying of myocarditis (93) and "Other forms" (95) only 48.7 were business and professional men, despite the fact that the ages of the two latter groups were higher.

The age distribution of coronary disease among men and women is shown in table 2. From this it appears that women die at an older age than do men. Among women 48.8 per cent were below seventy while among men 66.7 per cent were below seventy.

TABLE 2

CORONARY DEATHS IN BROOKLINE 1900-1935
ACCORDING TO AGE AND SEX

	Total Deaths	% 20-44	% 45-59	% 60-69	% 70+
Men	299	7.4	26.8	32.5	33.3
Women	162	1.9	9.9		61.3

The rates for coronary disease would have been much higher were it not for the fact that in Brookline women predominate sixty-one to thirty-nine. Computing the rates for each sex separately and for the ages over forty-five we find that in 1935 the rate was 811 per 100,000 men over forty-five and for women, 333.

HAS THERE BEEN A REAL INCREASE IN CORONARY DISEASE?

Obviously a large part of the increase of coronary disease noted in the death certificates is due to the fact that physicians are now diagnosing more cases of coronary thrombosis than formerly, but does this explain all the increase? Can we find any evidence in the figures that have been collected in this study to show that there has been an actual increase?

If there has been no real increase (or decrease) then the 1935 rate per 100,000 population 178.4 for angina and coronary disease combined, must have prevailed during the whole thirty-six years under consideration and the cases not diagnosed as such must have been diagnosed as some other form of heart disease and have been included in other subdivisions. We are probably justified in assuming that very few were diagnosed as endocarditis (91 and 92). The majority must then have been included under myocarditis (93) or "Other diseases of heart" (95).

In the chart the dotted line indicates the total of all other forms of heart disease if the 1935 rate for angina and coronary disease pre-

vailed throughout the whole period. It shows that the present rate for coronary disease is greater than the rate for all forms of heart disease in 1900-1904, and only slightly less in 1905-1909. It is therefore impossible that the present rate prevailed then. In the next two periods, 1910-1919 if the present rate prevailed there could have been no deaths from Myocarditis (93) or "Other diseases" (95). During the next three periods, 1920-1934 if we assume that the 1935 rate prevailed then we must also assume that during that period there has been an enormous increase of myocarditis and "other diseases", an increase for the two combined from a rate of 6.6 in 1920-1924 to a rate of 17.1 in 1935. This would be a very difficult increase to explain.

It may be that all forms of heart disease except endocarditis have increased during this period. That there has been a very definite increase in coronary disease the figures here presented certainly show. We must also realize that the number of deaths from coronary disease are much greater now than even the 1935 figures show, for as already pointed out there are still many deaths classified as myocarditis (93) and "other diseases" (95) which are really due to coronary disease. If these could all be included it is possible the rate of 811 per 100,000 men over forty-five in 1935 might be increased to 1000.

When we find that so many of these deaths are of persons in the prime of life—in men 66.7 per cent under seventy years of age—we must recognize that we have here a very large and important problem in preventive medicine toward the solution of which no helpful measures have as yet been suggested.

The first step in the solution of this problem is to determine why arteriosclerosis a process to be expected in the arteries in old age attacks the coronary arteries in certain persons at a relatively early age.

WHY THIS INCREASE OF CORONARY DISEASE?

The importance of this question is very generally recognized, and in the literature there is much discussion of it. Without attempting to review this it may be said in summary that most authors attribute the increase in coronary disease to worry and to the stress and strain of modern life—that is to a nervous and emotional strain. Thus White³ finds the increase in coronary disease "appalling" and believes "the most effective move we can make is to call a halt on the world's mad rush of today." Dr. W. J. Mayo⁴ has picturesquely compared the belief of the Ancients that the heart was the seat of the emotions with the modern idea that stern control of the emotions affects the coronary arteries of the heart. He points to the frequency of coronary deaths among surgeons who as a class must have stern control of their emotions.

Osler⁶, in his textbook, says of Angina Pectoris "It is not a disease of the working classes. The life of stress and strain, particularly of worry, seems to predispose to it, and this is perhaps why it is so common in our profession."

Many others besides Osler have called attention to the relative freedom from coronary disease of those doing manual work, but no explanation for this striking fact seems to have been offered. The obvious and striking difference between those groups of society who suffer least and those who suffer most has been largely ignored. This difference is that those who suffer least have occupations which entail a certain amount of *daily* physical activity, while those who suffer most have sedentary occupations which require a minimum of physical activity.

Granting that in those with sedentary occupations nervous and emotional strain may be a contributing factor, *is it not the sedentary life, the insufficient muscular activity, which is the basic underlying cause?*

If physical inactivity is an important factor in the development of coronary disease, then it would be logical to seek the cause of the increase in coronary disease in changes in the habits of the American people which had resulted in lessened physical activity and more sedentary living. On very brief consideration it will become apparent that such changes have taken place.

LIFE IN A MOTORIZED AGE

First and foremost is the use of the automobile. Everyone old enough to remember the "horse and buggy" age must realize what a tremendous change has come about. Almost everyone of the business and professional group walked more then than they do now. There was the walk to and from the electric car or train on the way to business. One did errands on foot—now one takes the auto to go half a block. Even social engagements in the evening meant some walking while now one goes from door to door in the car. People took walks in the country as a pastime, while now we "go places" in the car.

The medical profession was the first to use the automobile in a business way and has thus been longest exposed to its influence. At the present time medical men seldom use their legs except to follow a golf ball. It does not seem to the writer that the practice of medicine today entails any more strain than it did twenty-five years ago, and we cannot explain the increase of coronary disease in our profession in that way. The striking change in this period is the lessened physical activity of men.

In addition to the automobile there are various other labor-saving devices which have resulted in less physical effort. Elevators are in

more general use in stores, office buildings, and apartment houses. Oil heaters make unnecessary the shoveling of coal, life in apartment houses reduces the number of chores to be done, such as shoveling snow and caring for the garden. All in all, life for those with sedentary occupations has become much more sedentary.

There is reason to believe that walking is an especially good form of exercise for the heart. In the German spas which have a world wide reputation for the treatment of heart disease, graduated walking exercises have been used extensively in rehabilitating patients with damaged hearts. Paths are laid out and marked with different colors indicating the steepness of the grades on these paths. The grades to be climbed are carefully prescribed and before discharge the patient is often able to do considerable "*hill climbing*."

In general, one is safe in assuming that those hygienic measures that are of value in the treatment of a disease will also be useful in the prevention of that disease. Thus sunlight will not only cure but also prevent rickets. The hygienic measures used in the treatment of tuberculosis are also applicable for the prevention of that disease. By a similar analogy walking should be of value for preventing those forms of heart disease which are not of infectious origin.

GOLF AND CORONARY DISEASE

Apparently counteracting the lessened physical activity resulting from the use of the automobile has been the growing popularity of the game of golf among just that class of society that suffers most from coronary disease. One often sees reference in the literature to the frequency of coronary disease among golfers. Riesman and Harris⁷ state "The majority of coronary individuals are active and athletic, often passionate golf players." At first sight this seems inconsistent with the theory that physical inactivity favors the development of coronary disease. We must remember, however, that golf is not *daily* exercise. It is usually played only once or twice a week for a period of about six months and there follows an equal portion of the year when, with little or no reduction in the diet, the average golfer takes little or no exercise.

Golf should be an ideal form of exercise for middle-aged men and doubtless would be if golfers took regularly some other form of exercise—preferably walking—when they were not playing golf. It is obvious that playing golf for six months and then taking no exercise for six months is no protection against coronary disease and may perhaps promote it.

THE PREVENTION OF CORONARY DISEASE

With nervous and emotional strain, the only generally recognized causative factor in coronary disease, preventive medicine has been pow

erless. We cannot "call a halt on the world's mad rush of today." We have seen our most useful citizens carried off by this disease in increasing numbers and have not raised a finger to prevent others meeting the same fate.

While we can do little to reduce worry and nervous strain, we can control our physical activities. Once it is recognized that coronary disease results in part at least from lack of muscular activity we have a very definite point of attack. Obviously the need is for a campaign of education to teach the public (and the profession) that daily exercise is one of the essentials of health, that strenuous exercise taken occasionally or limited to only part of the year may be dangerous. Exercise should be a part of our daily routine.

The time is ripe for such a campaign of education for people are now really alarmed by the frequency of deaths from this cause and would grasp at any practical means of lessening the danger. The tuberculosis campaign has shown us what may be accomplished by education. As a problem in preventive medicine coronary disease is now much larger and more important than is tuberculosis. It is second only to cancer.

It is certainly the duty of the medical profession and especially of the cardiologists to consider seriously the question whether the lessened physical activity of the present day is not an important cause of the increase of coronary disease. If they find it is, the course to be followed is clearly marked.

SUMMARY

Previous to 1930 there was no subdivision for coronary disease in the International Classification of Causes of Death. To make figures available for coronary disease previous to 1930 the writer reclassified according to the 1930 Classi-

fication, all the deaths from heart disease in Brookline from 1900 to 1935.

There was a very marked increase of coronary disease during this period. In 1935 the rate for men was 811 per 100,000 men over forty-five, and for women of the same ages 333. Actually the rate is even higher as there are still many deaths due to coronary disease not diagnosed as such.

A part of the increase noted is due to the fact that coronary thrombosis is more frequently diagnosed now than formerly but this study showed that there must actually have been a very considerable increase.

The early appearance of sclerosis of the coronary arteries in certain individuals is most commonly attributed to nervous and emotional strain. Little attention has been paid to the fact that the disease is rare in men with occupations requiring daily physical effort and most frequent in those with sedentary occupations which suggests that physical inactivity predisposes to coronary disease.

The life of men with sedentary occupations has become even more inactive through the use of the automobile and other modern devices and this may well explain in part the recent increase in coronary disease.

To prevent coronary disease a campaign of education is needed to teach the American people that daily exercise is one of the essentials of health.

ONE HUNDRED AND FIFTY CASES OF TUBAL PREGNANCY*

BY BENJAMIN TENNEY, JR., M.D.

A STUDY has been made of one hundred and fifty cases of tubal pregnancy which have been treated on the Gynecological Service of the Boston City Hospital during the past eight years. The hospital records of the patients, the laboratory work and the pathological specimens in the Department of Pathology have been studied. From the data available a complete picture as possible has been drawn.

In regard to menstrual history, out of one hun-

dred and forty cases whose histories were satisfactory sixty-four or 45 per cent gave the story of having missed one period entirely. Eight had missed two periods and one had missed three. Therefore seventy-three or 52 per cent had missed one or more periods. Added to this twenty-five cases that had a very scanty period with just a little spotting and we have a total of 70 per cent. Jonas' figure of 60 per cent is quite close. A history of irregular bleeding previous to admission was given by one hundred and sixteen or 82 per cent. There were one hundred and sixteen or 77 per cent of the hundred and fifty cases that were bleeding on all

From the Gynecological and Obstetric Service of the Boston City Hospital.

(Tenney, Benjamin, Jr.—Junior Visiting Surgeon in Obstetrics and Gynecology Boston City Hospital. For reprint and discussion of author see This Week in Medicine, page 726.)

mission These last figures seem of especial interest as it stands out definitely that the acute type of cases and the more dangerous were those that did not show staining on admission They were the type that had been well until seized with acute abdominal pain generally within twelve hours of admission In this class fall most of the severe ruptures with internal hemorrhage The absence of bleeding indicates a living pregnancy up to the time of rupture and therefore a more potentially dangerous source of disaster Three of the five deaths from acute hemorrhage were not staining on admission.

The physical findings in the entire series gave one hundred and forty or 93 per cent whose chief complaint was lower abdominal pain usually worse on the side of the pregnancy but in many it was bilateral Abdominal tenderness was present in one hundred and twenty-six or 84 per cent Pelvic tenderness either localized or general was present in one hundred and thirty-nine or 92 per cent A pelvic mass was made out in ninety-one or 60 per cent There were forty-two cases or 28 per cent in which although a definite mass could not be outlined, there was a notation of bulging or fullness In other words there were only seventeen or 12 per cent that did not show either a pelvic mass or fullness An abdominal mass was palpated in eleven cases

Out of the entire series twenty-six cases or 17.3 per cent were primiparas In eighty cases in which the history was complete in this respect, thirty-eight had had a pregnancy within two years, nineteen within five years and twenty-three from five to twenty-five years A long period of sterility was not the rule in this series It was interesting to learn that forty-eight cases or 32 per cent had had previous abdominal operations of which all but seven were appendices or pelvic surgery This point has been emphasized by Lutzenberg² who however has the lower figure of 15 per cent Scheffey, Morgan and Stimson³ give 37.7 per cent which is close to our figures Only eighteen cases had a past history of pelvic inflammation but as that is a difficult history to obtain, I feel it fairer to rely on the pathological sections which show a much higher incidence Lutzenberg², however, finds in his pathological sections only 10 per cent definite salpingitis

Correct preoperative diagnosis was made in 79 per cent Fifteen cases were diagnosed as pelvic inflammation, seven cases as ovarian cyst, three cases as appendicitis, three as fibroid uterus, and two as pelvic abscess with threatened miscarriage In eight cases no definite preoperative diagnosis was recorded

LABORATORY

There were ninety-one cases in which a white blood count was recorded Of these, forty-seven

or a little over half were under ten thousand. There were nineteen cases between ten and fifteen thousand There were twenty-five cases in which the white count was higher than fifteen thousand Of these twenty-five, twenty one were of the acute type with symptoms of less than twenty-four hours' duration Of these twenty one all showed general abdominal tenderness and spasm and all had considerable free blood in the abdomen at the time of operation The majority of these were not bleeding on admission In other words, the high white count indicated acute rupture with internal hemorrhage of considerable amount and of recent origin. The other four cases had had symptoms from one week to a month with some staining on admission However, they showed general abdominal tenderness and spasm with fresh blood in the abdominal cavity, in other words an acute hemorrhage on top of previous minor bleeding

Of particular interest is the sedimentation rate that was done on thirty-six cases There were twenty-two cases that had a sedimentation time of one hour or greater Eleven cases were between thirty minutes and one hour There were only three cases under thirty minutes This certainly indicates that the sedimentation rate is a valuable point in differential diagnosis of pelvic infection and hemorrhage from tubal pregnancy Pelvic inflammation with symptoms sufficiently acute to be confused with ruptured tubal pregnancy usually shows marked lowering of the sedimentation rate

An Aschheim-Zondek test was done in eighteen cases In the case of acute rupture with internal hemorrhage there is not the time or need for such a test The diagnosis is usually fairly definite and if not positive, at least shows an acute abdominal condition that needs surgery In the case with pain and a pelvic mass but no acute symptoms, the Aschheim Zondek test is of immense value In spite of the small number of tests, the definiteness of the findings was of considerable value Of the eighteen cases eight tests were positive In the microscopic study of these every one showed actively growing trophoblast (fetal cells) In three cases the placental villi were necrotic or absent This coincides with the belief as shown in hydatid mole and chorio-epithelioma that the hormone is dependent on the trophoblast and not the fetus In two cases with sections of the ovary a good corpus luteum was found In the other ten cases the Aschheim-Zondek test was negative In these ten cases no living trophoblast could be found in any of the sections The sections generally showed organized blood clot containing hyalinized placental villi and occasional trophoblast cells in a degenerated and necrotic state In six cases there were sections of the ovary and in none was there any trace of the corpus luteum of pregnancy The value

of the Aschheim Zondek test appears to be this. If the test is positive, it indicates that there are living, growing and invading fetal cells present which give a definite danger of rupture of the tube, of hemorrhage or of both. On the other hand if the test is negative, the danger is less acute with a much slighter chance of internal hemorrhage. It is also important to note that a negative Aschheim Zondek test simply excludes a living tubal pregnancy and does not rule out a dead tubal pregnancy as the explanation for what symptoms may be present.

PATHOLOGY

In reviewing the reports on the gross pathology of the specimens it is quite difficult to classify the cases as rupture or abortion. However, there were seventy nine cases or 72 per cent that showed definite perforation or rupture of the tubal wall. There were thirty four cases described as intact. By this is meant cases in which there was no perforation of the tubal wall and no evidence of extrusion of tubal contents from the tubal ostium. There were thirty seven cases with no sign of perforation of the tubal wall and evidence of extrusion of tubal contents from the ostium. I agree with Litzberg² that a true and complete tubal abortion is rare. As shown by the microscope this type is practically always an incomplete tubal miscarriage. I also consider his term "internal rupture" excellent as it is rare not to find bleeding within the tube in the intact cases and the so-called abortions are simply a continuation of this process.

Out of the one hundred and fifty cases there were twenty embryos recovered including one pair of twins apparently of a single ovum each twin being about 2 cm in length. The embryos generally were found in the intact cases but some of them were recovered from the abdominal cavity following rupture. There was one interesting case of essentially an abdominal pregnancy where the placenta was attached to the appendix and cecum with the fetus growing free in the abdominal cavity. The fetus was approximately three months' size and well formed. There were two cases in which the patient claimed to have miscarried a fetus from the uterus previous to entry. In one case the fetus had been seen by the attending doctor. One certainly and both possibly were the rare condition of a double pregnancy.

The question of salpingitis as an etiological factor has been much discussed. Litzberg² gives his findings as 10 per cent positive and 10 per cent questionable. Schaffey, Morgan and Sampson³ as 30 per cent and Van Etten⁴ as 10 1/2 per cent, Sampson³ 36 per cent. In this series of cases a somewhat higher incidence was found. In the routine pathological reports thirty-eight cases or 25 per cent were diagnosed as salpingitis. In reviewing the slides with this point in

view I found fifty cases or 33 per cent with definite follicular salpingitis. There were two cases that showed tuberculous salpingitis.

In estimating the number of pregnancies that were living at the time of operation ninety six or 64 per cent showed living fetal trophoblast and fifty three showed no living fetal cells.

There were forty cases in which specimens of ovary were present. It was interesting to study the relation between trophoblast and the corpus luteum. In sixteen cases the pregnancy was dead with no living fetal tissue and no corpus luteum at pregnancy. The ovaries showed ripening follicles and four had a corpus luteum at menstruation. In eleven cases the pregnancy was in good condition with actively growing fetal tissue and a good corpus luteum at pregnancy. In four cases there was good trophoblast, no good fetal villi and degeneration of corpus luteum. In five cases there was an entirely degenerated corpus luteum and no living fetal tissue. In four cases there was good fetal tissue but no corpus luteum. Of course here the corpus might have been in the other ovary. It would seem from these studies that injury to the pregnancy causes first the death of the fetus. Death of the fetus is followed by degeneration of the corpus luteum. After the degeneration of the corpus luteum the trophoblast may continue to grow for a considerable time. This suggests a hormonal influence of the fetus on the corpus luteum. As we know that removal of the corpus luteum early in pregnancy causes miscarriage, it would seem that the life of the fetus is dependent on the corpus luteum and from the above that the corpus luteum depends on the fetus. Börner⁵ found that the corpus luteum begins to degenerate as soon as implantation of the ovum is disturbed.

The 'Influence of Ectopic Pregnancy on the Uterus' is well described by Sampson³. He found that only the cases of tubal pregnancy that did not have vaginal bleeding had intact uterine decidua. The termination of the pregnancy was based on the first attack of pain but termination was rarely complete at the time of operation. It would seem probable that the action of the tubal pregnancy on the uterine decidua was indirect, acting through the corpus luteum. The uterine bleeding is the sign of beginning degeneration of the corpus luteum caused by death of the tubal embryo. In this series there were six cases in which the uterus was removed. In two cases the tubal pregnancy was intact, the corpus luteum in good condition and the uterine decidua uninjured. In the other four cases there was no section of the ovary. However, in these cases there was considerable living trophoblast and villi in good condition. In one the endometrium was in the normal resting state and in the other premenstrual. In the third the endometrium was atrophic with uterine fibroids and in the fourth the decidua had mostly been cast off. These four cases had been

bleeding for several days. These few cases show that the original injury to the pregnancy causes beginning degeneration of the corpus luteum followed by uterine bleeding and that living trophoblast can survive for some time after.

In the entire series there were six deaths or a total mortality of 4 per cent. One case entered before operation with a temperature of 101°. She died eleven days postoperative of peritonitis and bronchopneumonia. Undoubtedly her death was primarily of infectious origin. The other five were all due to internal hemorrhage. Two of these had acute rupture with a three months' fetus found in the abdomen and died within a few hours in spite of all treatment. The third was a similar type with a four cm fetus. The fourth was so severely exsanguinated that she died on admission. The fifth was of interest in that she had been under observation for four days. Operation was decided on and she was given 500 cc of blood before operation. Immediately following the transfusion she went into shock. She was operated on immediately. The abdomen was full of fresh blood and she died on the table. This is a good example of the danger of transfusion starting a fresh hemorrhage.

SUMMARY

A study has been made of one hundred and fifty tubal pregnancies. The outstanding signs and symptoms of these cases were: seventy per cent had either missed a period or had a very scanty period. Eighty-two per cent gave a history of irregular bleeding. Seventy-one per cent were bleeding on admission. Some of the most acute cases were those that were not bleeding when seen. Three of the five deaths from hemorrhage were not staining on admission. Ninety-three per cent complained of lower abdominal pain. Pelvic tenderness was present in ninety-three per cent, pelvic mass or fullness in eighty-eight per cent.

A high white blood count indicated recent and considerable internal hemorrhage. The sedimentation rate in all but three cases was higher than thirty minutes. A positive Asch-

heim-Zondek test showed living fetal tissue that was still growing and invading. A negative test indicated that growth had ceased.

A study of pathological sections showed that injury to the pregnancy caused first the death of the fetus followed by degeneration of the corpus luteum. The trophoblast often continued to live for some time. The possibility of an hormonal influence of the fetus on the corpus luteum is suggested. Bleeding from the uterus is dependent on beginning degeneration of the corpus luteum which follows the death of the fetus.

CONCLUSIONS

1. The most consistent picture of tubal pregnancy is a history of a missed or scanty period, irregular bleeding, lower abdominal pain and pelvic mass or fullness, and pelvic tenderness.
2. Lack of staining may be a sign of danger.
3. A high white count indicates considerable internal bleeding. A normal sedimentation rate is in favor of tubal pregnancy.
4. A positive Aschheim-Zondek test indicates living fetal cells. A negative test shows death of fetal cells.
5. A study of the pathological specimens indicates that the fetus dies first, followed by degeneration of the corpus luteum. Degeneration of the corpus luteum causes casting off of uterine decidua with uterine bleeding. The trophoblast can continue to grow for some time longer.

CONGENITAL ABSENCE OF THE VERMIFORM APPENDIX IN A PATIENT WITH MENTAL DISEASE

BY L. W. DARRAH, M.D.*

CONGENITAL absence of the vermiform appendix is exceptionally rare. According to the ultracritical reviewers of the literature on this subject there are, seemingly, but twenty-eight authentic reported cases in the past two hundred and sixteen years! Other reviewers of this same literature, and who are just as ear-

nest as the ultracritical group, would extend this number to forty-nine. Therefore, because of such evident rarity, the following case found at autopsy—with no record or evidence of any operation—merits reporting.

Female, aged fifty-five, a patient in the Gardner State Hospital during the past nine years was diagnosed, schizophrenic, paranoid type. She was quite debilitated both men-

*Darrah L. W.—Assistant Physician, Gardner State Hospital. For record and address of author see This Week's Issue page 795.

tally and physically and died of gastric ulcer.

At autopsy June 20 1935, there was nothing significant in the thorax or in the abdomen except in the gastrointestinal tract. The stomach was very white and markedly distended and when opened, it contained a large amount of gas and a small quantity of grayish brown fluid. A perforating ulcer 2.5 cm. in diameter was found on the posterior wall, near the lesser curvature. The large bowel especially the sigmoid was distended and dark in color. The appendix could not be located. The anterior tenia said to be the surest guide to the process was followed as in Greco and Ross's case¹ to its termination at which point the cecum was smooth. The point of junction of the three teniae was thoroughly examined. Not even a rudimentary projection could be found. The serosal surface of the cecum was everywhere smooth. The retrocecal fold and fossa were also explored. The cecum was the usual loop-sided adult form with nothing else remarkable about its appearance.

It is more than interesting that this anomaly was first reported by Morgagni in 1719. Two hundred and sixteen years ago it was next described by Hunter² in 1762 and Haller³ in 1765. Still later Meckel⁴ in 1812, Ferguson⁵ in 1891, Roberts⁶ in 1896, Dixon⁷ in 1896, Swan⁸ in 1898, Fawcett and Blachford⁹ in 1899, Picquand¹⁰ in 1900, Michaux¹¹ in 1902, Huntington¹² in 1903, Marie¹³ in 1903, Dillard¹⁴ in 1903, Schridde¹⁵ in 1904, Marshall and Edwards¹⁶ in 1906, Looten¹⁷ in 1906, Froelich¹⁸ in 1910, Dailey¹⁹ in 1910, Shuels²⁰ in 1911, Velyaminoff²¹ in 1911, Lecomte²² in 1911, Bloodgood²³ in 1911, Hanseu²⁴ in 1912, Bérard and Buche²⁵ in 1913, Gladstone²⁶ in 1914, Dorland²⁷ in 1925, Maurer²⁸ in 1927, Jacob²⁹ in 1928, Bradley³⁰ in 1929, Spivack³¹ in 1931, Green and Ross³² in 1933, Sindoni³³ in 1933, Lonyot, Rachen, and Lacourt³⁴ in 1934 and Darrah in June, 1935.

According to the literature, examined at the Boston Medical Library and the Harvard Medical Library, on congenital absence of the vermiform appendix, the number varies between the ultracritical estimate of twenty-eight reported authentic cases, and forty-nine. Some writers reported two or more cases, some from anatomic and pathologic laboratories, Bird³⁵ and Bird Oliver and Robinson referred to by Dorland³⁶. So it is apparent that there is some disagreement, among the reviewers, as to the actual number of authentic reported cases.

Schridde, for instance when reviewing the subject in 1904, did not accept many of the earlier cases of agenesis of the vermiform appendix. His theory, according to Spivack is that 'the appendicular portion of the primitive cecum fails to become arrested in its development as it normally should but keeps pace in growing with the cecal portion proper and at maturity is indistinguishable as to caliber from a normal cecum. The reason why he

gave such an explanation was that in his case the cecum was of a child fifteen months old on the cecum were present six haustra instead of four. (As is known the human cecum up to the age of four or five years has deep furrows which subdivide the wall of the cecum into four haustra, these haustra normally disappear at the age of four or five years due to intracecal pressure of the fecal material, and the cecal wall then becomes smooth.) The fact that in his case there were six haustra instead of four and also the absence of the appendix, made him believe that these two additional haustra were the modified appendix. He explained on the basis of his specimen that normally the appendix is formed by the arresting of the lower two haustra that at some period of the embryonic stage all six haustra are of the same size and width, later on the lower two haustra are arrested in their growth and form the appendix and the upper four continue to grow and form the cecum. Therefore Schridde advised: 'Whenever there is a congenital absence of the appendix, count the number of haustra.'

This sounds interesting. But according to Spivack, in order to corroborate it, one has only to deal with such a cecum where the haustra are present which occurs only in cases of children up to four or five years. In grown persons there are no haustra, and dealing with an absence of the appendix in a grown person one can neither corroborate nor disprove this theory unless one comes across a case of absence of the appendix in a grown person with an infantile type of cecum. It seems that Schridde had but one such case, and Spivack had one. Obviously, if the former's theory be accepted, then apparently there are but two authentic reported cases of agenesis of the vermiform appendix!

But it will be seen further on in this article that Schridde's drastic reduction of cases is set aside by Bradley's study of the embryological development of the cecum and it receives the support of reputable anatomists.

Dailey, when examining the literature in 1910 would accept only ten of the twenty six reported cases up to that time. He cautioned that "one should not be too hasty in publishing alleged cases of absent appendix for there are many possibilities of error." Dorland reviewing the literature at a still more recent date (1925) accepted thirty seven cases as authentic. Bradley in his informative article published in 1929 at that time accepted forty cases. He quoted Kelly and Hurdon³⁷ who state that the appendix is "merely a portion of the general cecal pouch which has remained in an early stage of development." Writes Bradley, "It is formed from the terminal portion of the cecal pouch from which it is at first indistinguishable. Differentiation takes place in two stages

A primary stage occurs at about eight weeks when a distinction can first be made between a larger proximal portion (cecum) and a smaller distal portion (appendix). A secondary stage occurs at about the time of birth, coincident with the formation of the teniae, when a more marked disproportion between the size of the cecum and that of the appendix becomes evident. Development may be interfered with at any stage. The resultant anomalies have been postulated (by Bradley) as follows:

THE ARRESTED DEVELOPMENT OF THE CECAL POUCH AND THE RESULTANT ANOMALIES

<i>Stage of Growth</i>	<i>Anomaly</i>
Failure of the cecal anlage to develop	Absence of cecum and appendix
Partial development of cecal anlage	Rudimentary cecum without the appendix
Full development of the cecal portion, no development of the appendiceal portion	Normal cecum, no appendix
Normal early differentiation of the appendix, but early discontinuance of development	Normal cecum rudimentary appendix
Normal early development but failure of appendiceal portion to become differentiated, its growth keeping pace with that of the cecal portion so that a differentiation is not evident	Normal appearing cecum probably with extra haustra, as in case reported by Schridde, no appendix

In 1930, Spivack skimmed the literature and wrote, "This makes a total of forty-four cases and my cases are the forty-fifth and forty-sixth." Yet Spivack evidently had some uncertainty about his figures, as he observed that some of the reported cases were hypoplasia. Excluding these, and those where the appendix was not found but in which there were adhesions around the cecum, then the cases of actual agenesis of the appendix could be cut to nearly half.

"Probably," wrote Spivack, "it would be closer to the truth to say that only about twenty-five cases were undoubtedly true agenesis."

And in 1933, when Green and Ross studied the literature, they too agreed with Spivack's minimum—twenty-five—to which they added their own, the twenty-sixth.

In December, 1933 Baldwin³⁸, after reading Green and Ross's report, examined Bradley's, and Spivack's, review, also several older ones, then quoted Scott³⁹, who boldly asserted in 1897 that the appendix is never absent, and that failures to find it have been due to improper search. According to Baldwin, Scott was then Professor of the Principles of Surgery, in the Cleveland College of Physicians and Surgeons, etc., at the time he published an account of a seeming case with a photograph of the specimen. Scott claimed that his own case, and all other reported cases, were merely appendicitis obliterans totalis. Briefly, he located

the appendicular artery and tracing that up found ample evidence of the previous existence of the appendix.

In the literature there seems to be no other reference to Scott's paper, and Baldwin explains that the paper was published in the bound volume of the Transactions of the Ohio State Medical Society for that year (1899), and distributed only to paid-up members, and for that reason was practically buried.

Scott's refutation is interesting. It may be that some of the reported cases did have hidden, microscopic vestiges of the appendix. Yet there is proof and authority for total, complete absence of the vermiform appendix. In 1929 there were four known specimens in museums. (There may possibly be more now.) Two are in the Museum of the Royal College of Surgeons, London, and two in New York's Columbia University Museum.

Anatomists agree that it is possible. Spitzka⁴⁰ wrote, "In rare instances the appendix has been absent." Piersol⁴¹ states, "The total absence of the appendix is extremely rare, but has been observed by ourselves and others." And Hertzler⁴² goes so far as to say, "No one has ever seen a 'normal' cecum except the one depicted in the textbook of his student days."

As has already been mentioned, Bradley has shown in his interesting table on embryological development of the cecum, that not only can the appendix be absent, but the cecum also. (This was shown by Froehch's reported case¹⁹ in 1910 being in complete agreement with Bradley's study.)

It is true, of course, that cases found at autopsy can be examined far more readily than those found during a surgical operation. To verify, on the operating table, the absence of the appendix in case it is not seen at the place of union of the three teniae, Spivack advises that one should mobilize the cecum from the lateral side and examine its posterior wall. And certainly Green and Ross, in their reported surgical case, searched exhaustively. So have other investigators.

After all, why should there be any doubt as to the possibility of absence of the vermiform appendix? Complete absence of the eyes has been recorded. Also complete absence of teeth from birth till death, also absence of feet, bilateral absence of the external ears, congenital absence of the tongue, of the gallbladder, and but one kidney.

SUMMARY

The writer of this paper, in reporting his own case found at autopsy, records that the entire bowel was carefully dissected out, in an attempt to locate the appendix, or find a vestige of its existence. Five other physicians were present and assisted in the search for the appendix, and were finally convinced that here was a case of total congenital absence of the vermiform appendix.

Therefore, this case, if based on the ultracon servative opinions of Schridde, Dailey, Spivack, and Green and Ross, would be approximately the twenty ninth. But if based on the figures and studies of Dorland, and of Bradley it would appear to be the fiftieth

THE OCCURRENCE OF ALLERGIC REACTIONS IN ARTHRITIC PATIENTS*

BY ALBERT G. YOUNG, M.D.†

FOR several years investigators have speculated on the possible relationship of Atrophic or Rheumatoid Arthritis to a bacterial allergic reaction. Terry¹ in 1915 and later Zinsser and Griaell² 1925, and Swift, Derrick and Hitecock³ in 1928, introduced findings that suggested a bacterial allergic reaction in both rheumatic fever and rheumatoid arthritis. Rackemann⁴ in 1933, reviewed the literature and gave an excellent critical résumé of the work bearing on this subject. He also pointed out that in his experience hay fever and oshtmatitis patients did not show an unusual incidence of arthritis.

The writer in studying arthritis has worked

on the allergic hypothesis⁵, and in presenting his studies has routinely inquired (while taking the history) into hay fever, asthma, food and drug sensitization, migraine, urticaria and dermatitis. The histories also included records of focal or general infections (past or present), and whether the onset of the arthritic symptoms was associated with infection, overwork, trauma, etc. In so doing I was impressed, first, with the high incidence of clinical allergy reported by my patients and secondly, that most of them reported the presence of some infection, single or repeated antedating the onset of the arthritis. Recently I have studied the case histories of 200 private patients with rheumatoid arthritis, in whom the onset of symptoms (as shown by the present illness in the history) was sufficiently acute for the patient to be able to state quite accurately its relationship to infection.

From the Department of Pharmacology and Therapeutics of Boston University School of Medicine.
†Young, Albert G.—Assistant Professor of Therapeutics, Boston University School of Medicine. For record and address of author see "This Week's Issue," page 796.

contributing factors These findings have been tabulated and compared with the records of fifty non-arthritic patients, fifty patients with allergic dermatitis and fifty patients with urticaria. In making this comparison the attempt has been made to gain information concerning (1) Whether arthritic patients show a greater incidence of allergy than the average group of clinical patients, (2) if so, what type of allergy predominates, (3) what is the most common condition associated with the onset of the disease, and (4) what is the incidence of arthritis in patients with allergic diseases

Because of the work of Rackemann⁴, and Harkavy and Hebal⁵, who reported a low incidence of arthritis in hay fever and asthmatic patients, I did not study this phase of the problem

RESULTS

Table 1 shows that of the 200 patients stud-

thritic patients are more susceptible to skin allergy than the average clinical patient

The next question was what per cent of patients suffering from allergic dermatitis and urticaria had arthritis. An examination of the records of fifty cases of allergic dermatitis (table 2) or venenata, showed that two patients (4 per cent) had arthritis. None had a question or a past history of arthritis. The records of fifty cases of urticaria showed one case (2 per cent) of arthritis and none with a question or a past history of arthritis. This makes a total of 6 per cent of arthritis among 100 patients suffering from skin allergy, as compared with 31.5 per cent of skin allergy in 200 arthritic patients.

A study of the relation of infection to the onset of the disease was undertaken. Care was taken in each instance to determine when the bacterial infection occurred in relation to the onset of the arthritis. If the upper res-

ied, 6.5 per cent had hay fever, 7 per cent had asthma and 1.5 had both conditions so that actually 15 per cent had a present or past history of hay fever or asthma, or both. Urticaria was found in 15.5 per cent and allergic derma-

piratory, or dental infection, etc., incident was more than eight weeks previous to the onset of the arthritic symptoms the case was not used for this study, since it would be unusual for anyone to attain the age of twenty-five or thirty

titis in 16 per cent, making a total of 31.5 per cent showing skin allergy.

For comparison I then began a search to determine what percentage of non-arthritic patients with a chief complaint other than that of an allergic disease, had hay fever, asthma, urticaria, or allergic dermatitis. Fifty non-arthritic records (table 1) disclosed a past or present history of hay fever in four patients (8 per cent) and asthma in three patients (6 per cent), making a total of 14 per cent as compared with 15 per cent of the arthritic patients, urticaria in five patients (10 per cent) and allergic dermatitis in one patient (2 per cent), making a total of 12 per cent as compared with 31.5 per cent in the arthritic patients.

From these findings it would appear that ar-

years without having some upper respiratory or dental infection, to say the least. Care was also taken to rule out upper respiratory or dental infection which occurred after the onset of the arthritis. This does not mean that infections occurring two months prior to the onset of arthritis are not considered as pertinent to the development of the disease, but for the reason stated above it was necessary to draw an arbitrary line if the findings were to have any value in this study. The results showed, that at the time of, or immediately previous to the first symptoms, sixty-eight (34 per cent) had infected teeth, eighty-four (42 per cent) had sore throat, sixteen (8 per cent) had infected sinuses, four (2 per cent) had middle ear infection, one (5 per cent) had ruptured appen-

dix. and two (1 per cent) had a nonspecific prostatitis. This makes a total of 875 per cent in whom an active infection was associated with the onset of the disease. In the remaining 125 per cent a history of exposure to dampness and cold overfatigue trauma, etc., was recorded.

Skin tests on twenty patients to food and bacterial proteins were of little value so far as linking up the skin sensitization with the arthritis. This corresponds with the work of Deriek and Fultou⁷ who found positive skin reactions to food and bacterial proteins to be as common in adults who were not suffering from arthritis as in the arthritic patients.

One interesting observation was made in this respect. Even in cases where a known food sensitization was present the patients' joint symptoms were not influenced by eating the foods to which they were sensitized. This experiment was repeated several times on about fifteen patients who suffered with a pronounced urticaria or dermatitis following the ingestion of certain foods. At no time did they present any increased objective findings, nor did they complain of increased symptoms during the time of the skin reaction.

DISCUSSION

These results do not strengthen the contention of some investigators who attribute the etiology of arthritis to dietary disturbance. Some of the findings are very interesting in the study. First, the results show an unusually high percentage of skin allergy either past or present in the arthritic patients, whereas patients suffering primarily from a skin allergy do not show an unusual incidence of arthritis. This indicates that while arthritis appears to predispose to skin allergy, the reverse is not true. And secondly, the incidence of focal infection in relation to the onset of arthritis is too high to be disregarded. It lends strength to the hypothesis of bacterial allergy.

Just why the asthmatic and hay fever patients do not show a high incidence of arthritis may be answered by Rackemann's explanation and also it is pertinent to the findings mentioned above relative to the incidence of skin allergy in arthritis. In discussing Harkavy and Hebbald's⁸ findings of 2.25 per cent of arthritis among 400 children with asthma, he says: "Evidently the relation of Arthritis to this particular form of allergy is very doubtful. But the word 'allergy' is also used in connection with other reactions which are not immediate but delayed which give rise not to urticarial wheals, but to areas of inflammation."

He then points out that at least a theoretical relation exists between the two, namely the work of Zinsser and others indicates that the urticarial reaction typical of hay fever and asthma represents the early phase of the immune process, whereas the inflammatory tuberculin type

of reaction represents the late inflammatory phase. He believes the mechanism in arthritis to be closely related to that in asthma, but that in both conditions the fundamental feature is not the particular agent but the reaction of the host toward the reagent.

Rackemann's opinion is further substantiated by the findings of Young and MacMahon⁹ in which it was demonstrated that the pathological lesions in arthritis and rheumatic fever were identical, and concluded that "This complex histological picture is simply one of a non-specific chronic inflammatory reaction showing regressive, exudative and proliferative changes, but no structural lesions diagnostic of rheumatic infection."

In view of the frequent references made to tuberculin allergy in speaking of arthritis, it is interesting that while making the above study (Young and MacMahon) a section from a case of tuberculosis of the joint was obtained which showed the same microscopic changes that were described in the arthritic and rheumatic patients. I consider this an inflammatory allergic reaction which is not specific for any one organism. This is in keeping with the view expressed by Birkhaug¹⁰ who said: "It seems justifiable to postulate that the exquisite allergy to streptococcal products is resultant from oft repeated upper respiratory low grade infections. The question arises whether or not one or several strains of streptococci are responsible for the early sensitization of the individual."

I would carry this hypothesis farther to include prolonged or oft repeated low grade infections anywhere in the body. Furthermore while the streptococci appear to be the most common offenders, we cannot entirely disregard the possibility of other organisms especially the staphylococci and gonococci as sensitizing organisms. It is also important to consider the sensitization as being brought about by the broken down products of the bacteria rather than by the bacteria *per se*. This idea is consistent with the variations in the results reported on blood cultures in this disease.

SUMMARY

- 1 In 200 patients with rheumatoid arthritis 15 per cent gave a history of past or present hay fever or asthma or both and 31.5 per cent gave a history of allergic dermatitis or urticaria.
- 2 In fifty non arthritic patients 14 per cent gave a history of hay fever or asthma, or both, and 12 per cent gave a history of allergic dermatitis or urticaria.
- 3 In fifty patients with allergic dermatitis 4 per cent had arthritis.
- 4 In fifty patients with urticaria 2 per cent had arthritis.

any specific effect through the urine when used to arrest hemorrhage from the genito-urinary tract.

Our personal interest in Congo red as a hemostatic agent, is based upon its apparent usefulness in the control of hematuria. We have employed it for the relief of bleeding in such cases as the following: Renal injury, bilateral renal and ureteral calculi, chronic pyelonephritis, vesical calculus, benign hypertrophy of the prostate, tumor of the bladder, urethral trauma, etc. In fact, we have become so convinced of its value that the administration of Congo red is common in our clinic in all cases of active urinary hemorrhage, in conjunction of course with such other specific measures as may be indicated in the particular problem. No blood studies have been made to determine changes in coagulation time or in the platelet count and we have made no attempt to study the behavior of the dye in the production of hemostasis.

There have been no untoward effects in any instance, following the injection of Congo red in our cases. Five cc (1 ampule of a sterile isotonic solution) or 10 cc given intravenously constitutes the usual dose. This may be repeated if necessary. Rossak states that occasionally patients complain of palpitation and lower abdominal pain, but we have not observed such disturbances. Even the accidental perivascular injection of the dye has resulted in no ill effect, other than a persistent red discoloration of the skin.

In conclusion, it is our feeling that intravenous Congo red is a valuable adjunct in the treatment of hemorrhage from the urinary tract. We believe, however, that it is most useful in cases of acute bleeding in individuals who still possess at least relatively normal coagulation mechanism. We have found it, as might be expected, less effective in such chronic persistent bleeding as often occurs, for example, from pyelonephritis or malignant tumors of the urinary bladder. Whether its lack of success under such circumstances is due to local or general causes, we are unable to state. Obviously it will be of little or no value in actual blood disease (We have seen it employed without benefit in one case of purpura). We have used it, frequently, as a prophylactic agent following prostatectomy and transurethral resection, when unusual bleeding had been encountered. It is of interest also that some of our colleagues have administered it with marked success in such acute conditions as severe epistaxis and hemorrhage after tooth extraction.

METHOD OF APPLYING A TEMPORARY ADHESIVE SUPPORT TO THE BACK

BY THOMAS H. PETERSON, M.D.*

In the past a great deal of unnecessary pain has been produced through attempts to strap or immobilize individuals who are suffering from back pain due to injury or to some other cause. Below is described a method of doing this which was suggested by the late Dr. Robert Soutter and which allows the doctor to apply support to an individual suffering from a very acute back pain without requiring the patient either to turn over in bed or, as some have been required, to stand. The minimum discomfort to the patient is produced by Dr. Soutter's method and a support is applied which will hold far more firmly than an ordinary binder.

We have had the opportunity of using this type of apparatus frequently in acute back and sacro-iliac strains with good results. It has been used a number of times in separation of the symphysis pubis during pregnancy and in postpartum women. We have also used this type

of support several times in fractures of the pelvis, both as a temporary support and also occasionally as permanent supportive apparatus during the healing of the fracture. In its application in separation of the symphysis pubis, whether of traumatic or spontaneous origin, pressure should be applied below the anterior superior spine of the ilium.

A further advantage of this particular method over the usual type of strapping is that it may readily be taken off either during the care of the patient or for the application of physiotherapy, which is often desirable. It is, of course, impossible to apply physiotherapy measures to a back covered with adhesive with much hope of any therapeutic benefits, not only because of the danger of burning but also there is little chance of effecting results. Since the adhesive strapping on this type of binder is not in contact with the body, no excoriation or abrasion can result from its application and the skin is left in condition for whatever physiotherapy measures are deemed necessary.

*Peterson, Thomas H.—Junior Visiting Surgeon, Boston City Hospital. For record and address of author see "This Week's Issue," page 795.

For this method, an old binder or swathe, twelve inches wide, and long enough to encircle the patient with an overlap of about six inches, is procured. To this are applied strips of adhesive tape one and a half inches or two inches wide and of the same length as the binder, put on in parallel lines one eighth of an inch to one fourth of an inch apart, with the adhering side next to the binder. As a general rule six strips are sufficient for the ordinary strapping. We

- 1 Left end of binder overlaps right end
- 2 Right adhesive strips drawn across left end of binder
- 3 Left adhesive strips drawn across right adhesive strips

now have a swathe or binder with five or six adherent strips applied to the outer side.

In applying this support the patient is made to lie on his back and is then gently rolled onto one side. The binder is tucked under the patient's back with the cloth side next to him; he is then rolled onto the opposite side and the binder pulled through and smoothed down flat. The patient is now rolled back so that he is lying flat on his back. The binder with the cloth next to the skin is beneath him, the long axis of the binder at right angles to the long

axis of the body and at a level of the greatest discomfort.

Now the adhesive strips are pulled back from either end of the binder for about twelve inches and are laid out flat to be easily picked up again. The two ends of the swathe and binder are pulled across to overlap each other like the overlapping of a double-breasted overcoat (the left end overlapping the right) and are adjusted as snugly as is desirable or as the patient can comfortably stand. The adhesive straps are then brought across from the right end so that they now overlap the left end of the swathe in front. Each strap is brought across separately and applied to the swathe separately. In this way the necessary adjustments of the swathe may be made so that it will fit smoothly and all loose folds taken up. As a final step the loose end of the strapping, namely the left end, is brought across the now adherent right ends overlapping and adhering securely.

We now have produced a firm binder which fits very comfortably, conforming well to the contour of the body, because of the individual adhesive strips, and applied much more firmly than an ordinary swathe. It has the added advantage of not having injured the skin as the taping never comes in direct contact with the skin.

SUMMARY

This type of strapping is devised for very acute backs and back injuries. It is easily applied to a patient lying on his back with the minimum discomfort. It may be applied more firmly than an ordinary binder. It is easily and comfortably removed for physiotherapy treatment and reapplied with equal simplicity. It does not necessitate the direct application of adhesive plaster to the skin which, in itself, would frequently contraindicate the use of physiotherapy measures.

THE SOCIAL SECURITY ACT

Under the terms of the Social Security Act, the Federal Government matches the expenditures of States with approved plans for assistance to the needy aged and the blind up to a combined total of \$30 a month per person and contributes five per cent additional for administrative purposes. For aid to dependent children, the Federal grant to States with approved plans is one dollar for every two dollars the State spends up to a combined total of \$18 per month for the first dependent child in any one family and \$12 per month for each additional child in the family. Each State decides for itself which of its aged blind or its dependent children are entitled to aid and how much aid shall be given.

To be approved by the Social Security Board, a State public assistance plan must provide for cash payments to needy aged persons, to dependent children living with relatives, or to needy blind in all

parts of the State. A single State agency must administer the plan or supervise its administration if it is directly administered by the counties. This State agency must grant to any individual denied assistance the opportunity for appeal from the decision of the county denying him such assistance.

Thirty States and the District of Columbia now have public assistance plans conforming with the requirements of the Social Security Act. More than half a million individuals in these thirty-one jurisdictions receive assistance in the form of monthly cash payments under the cooperative Federal State system of aid provided for in the Act.

A NEW INSTRUMENT—AN ANTI ADHESION
PNEUMOTHORAX NEEDLE

BY CLEVELAND FLOYD, M.D.*

THE production of artificial pneumothorax is not uncommonly attended with great difficulty on account of the presence of pleural adhesions. These are encountered in many cases because of the fact that pulmonary tuberculosis develops from an initial lesion at the periph-

The calibre is that of the pneumothorax needles now in use.

Its advantages are, that the blunt stylet can be carried about three eighths of an inch beyond the end of the needle after it has entered the chest cavity and thus allows for separation of the visceral and parietal surfaces of the pleura.

ery of the lung. Where the pleura is directly involved and an effusion follows many pleural strands appear and often an adhesive pleuritis occurs with partial obliteration of the pleural space. Many cases of phthisis, that could be benefited by artificial pneumothorax are abandoned after futile efforts to find a free space. The anti adhesion pneumothorax needle is designed to meet this need.

Floyd, Cleveland—Physician-in-Chief, Division of Tuberculosis, Boston Health Department. For record and address of author see "This Week's Issue," page 736.

The double lock for the stylet at its base permits its being held securely in this position. With the stylet in place the calibre of the needle barrel allows the passage of air through the needle and into the chest cavity.

The separation of the pleural surfaces not only brings about a high percentage of successful cases, but the opportunity of forcing air into the lung and producing an air embolus is greatly diminished and thus the safety of the procedure is measurably increased.

THE ELLA SACHS PLOTZ FOUNDATION
FOR THE ADVANCEMENT OF SCIENCE

During the twelfth year of the above designated Foundation seventy applicants for grants were received. Thirty-four of this number came from the United States. Of the twenty-five grants made during this year thirteen were to scientific men in the United States. In the twelve years of the existence of this foundation it has distributed two hundred and fifty-two grants.

Of the number who have been aided in research work this year Dr. William Dameshek of Boston received recognition for his work on blood pigment metabolism in lead poisoning. Dr. Charles Lund of Boston for studies on the hormone intermediate and Dr. Yellapragada Subbarow of the Harvard University Medical School for his work on the isolation of materials.

The Thorndike Memorial Laboratory, Boston City Hospital, of which Professor George R. Minot is the Director has had a continuing grant since 1921 in recognition of Dr. Francis W. Penbody's service to the Foundation.

Applications for grants for the year 1936-1937 must be in the hands of the Executive Committee before May 1, 1936. They should be sent to Dr. Joseph C. Ann, Huntington Memorial Hospital, 895 Huntington Avenue, Boston.

PHYSICAL EXAMINATIONS FOR CITY
EMPLOYEES

The Municipal Civil Service Commission of New York City is considering the advisability of providing annual physical examinations for the 80,000 city employees.

The purpose of the plan is to raise the efficiency of the large number of people employed many of whom are neglectful of health or disinclined to spend the required amount incident to a doctor's fees. Together with the yearly examination the advisability of including free treatment is under consideration.

The arguments in favor of this plan are based on the experience of industrial organization where it has been shown that care of the health of the workers has an improved efficiency of the service that money has been saved. Other large cities may be interested in observing this experiment.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 22161

PRESENTATION OF CASE

A fifty-five year old white single woman was admitted complaining of jaundice.

The patient had been perfectly well until three years before entry. At this time she had two attacks of very severe sharp right upper quadrant pain which radiated through to the back and was associated with nausea, vomiting, and very slight jaundice. The duration of each attack was about ten days and both attacks subsided following the local application of ice. She continued well until one year prior to admission when she noted gradual loss of weight. Six months later she had three or four attacks of slight jaundice associated with chills, fever, vertigo, and mild pain in the epigastrium and right upper quadrant. Six weeks ago jaundice appeared and within a week it had become quite intense. A week later unbearable itching developed. She consulted her local physician who prescribed medication and a dietary régime under which her weight dropped quite rapidly. With this attack of jaundice there was no nausea or vomiting but the patient had considerable gaseous eructation and slight epigastric discomfort. The stools became clay-colored, and she developed constipation. The urine became darker in color. Increasing readiness of fatigue was attributed by the patient to dietary restriction. Her total loss in weight during the preceding year was 30 pounds. Generally she did not feel too badly.

The patient had had typhoid fever thirty-eight years before entry. The menopause occurred three years ago.

Physical examination showed a middle-aged woman who was quite deeply jaundiced, rather poorly nourished, in no great discomfort. The sclerae and conjunctivae were markedly icteric and the head and neck were otherwise negative. The heart sounds were of good quality. There was a soft systolic murmur at the apex. The blood pressure was 128/70. The lungs were clear. The abdomen exhibited normal respiratory excursions. There was no tenderness or rigidity. There were no masses palpable. The liver, spleen, and kidneys were not palpable.

Rectal and pelvic examinations were negative. The extremities were negative.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red cell count of 3,830,000, with a hemoglobin of 75 per cent. The white blood cell count was 7,200. The nonprotein nitrogen of the blood was 25 milligrams per cent. A Kahn test was negative. The icteric index was 100. The serum bilirubin was 4.9 milligrams per cent. The stools were definitely clay-colored and tests for occult blood were negative.

A flat plate of the gallbladder region revealed no stones. A gastrointestinal series showed a smooth notch on the greater curvature of the antrum which was probably due to adhesions. There was a large pressure defect on the lesser curvature which was thought to be probably due to gallbladder pressure. The remainder of the duodenum was normal.

In view of the persistent jaundice, operation was decided upon. The patient withstood the operation fairly well, but postoperatively her appetite and strength did not return so quickly as would be expected and she seemed to be slowly getting weaker in spite of the fact that her jaundice was clearing somewhat. After the second week she lost ground noticeably and died about the third week after operation.

DIFFERENTIAL DIAGNOSIS

DR. TRACY B. MALLORY: My role in the presentation of this case is somewhat of a novelty and requires a word of explanation. It was selected from the records of the City Hospital so that I could not possibly know the postmortem findings and I have contracted to attempt the clinical side instead of the pathologic. I am not doing this with any idea of setting an example of how it should be done but just to show that I am not afraid to "take the rap."

We have here a woman of fifty-five with an apparently obvious history of biliary colic on two occasions followed by a period of good health and then the onset of a final illness which lasted about a year. It suggested in the story, and if it is correct I think it is very important, that she began to lose weight nearly six months before the jaundice appeared in this final illness. The jaundice this time is evidently different from that of the two previous occasions. This time she had no pain and instead of being a mild transient jaundice it is a rapidly developing progressive affair. The stools were clay-colored and the urine was dark, apparently. The stools I should assume were uniformly clay-colored, that is, she was getting no bile through at all. So that we have a strong presumption that the jaundice is obstructive.

The physical examination hardly helps us at all. It confirms the jaundice, and the surprising thing is that nothing could be felt in the abdomen, not even the liver, spleen or kidneys.

The laboratory examinations tell us that she had an anemia, apparently of the secondary type, that she did not have any leukopenia, and they confirm the jaundice and the lack of bile pigment in the stools. It seems to me that essentially we have the differential diagnosis of painless jaundice.

Can this be cirrhosis? The fact that all bile pigment is absent from the stools seems to me rather strongly against that diagnosis. We have nothing in the way of positive evidence to point to cirrhosis. They did not feel the liver as they would have if it had been hypertrophic biliary cirrhosis. They could not feel the spleen as they reasonably might have if it had been atrophic cirrhosis with portal obstruction. She did not have leukopenia, which again I would expect with atrophic cirrhosis. The anemia moreover, was not noticed to show a high color index or to be macrocytic. It seems to me we have nothing in favor of cirrhosis as the primary disease.

Now can we explain the picture with a stone? We have every reason to suppose she had a gallbladder that contained stones. One might have slipped down into the common duct. So far as the jaundice and the absence of bile in the stools are concerned there is no inconsistency. It is perfectly possible that she might not have pain with it, although unlikely. If she had a stone completely obstructing the common duct I would rather expect a big liver that the bile would have been dammed up behind the stone and would have led to so-called hydrohepatosis, dilatation of the bile ducts and secondary swelling of the liver. That does not have to occur however. I have the impression that when obstruction in the biliary tract develops rapidly enough you sometimes do not get distention of the liver just as with ligation of the ureters you do not get hydronephrosis but the absence of liver enlargement nevertheless seems to me a point slightly against stone. I do not see how you can rule out stone with any certainty in this case and for that reason I think the surgeon would be not only justified in operating on the patient but obligated to do so. On the other hand I think he would stand a very slim chance of finding a stone in the common duct.

One other common lesion to consider would be malignancy and it seems to me that is strongly suggested by the history of thirty pounds loss in weight which I think we can trust the history, started before the jaundice appeared. If it is malignancy we have to try to decide where it is located. I do not believe it is primary cancer in the liver because hepatoma occurs in this country only in patients with cirrhosis and,

since I have already pointed out that we have no evidence of cirrhosis, I certainly cannot make that diagnosis. It might be a primary cancer of the intrahepatic bile ducts. It would have to be pretty strategically placed right at the hilum, to catch both the hepatic ducts and cause complete obstruction without being big enough to enlarge the liver. When we consider the last paragraph we find that the surgeon did something which was followed by a temporary relief in the jaundice and with cancer that far up it would have been practically impossible to do anything that could have relieved it. It might be lower down in the bile ducts, in the common duct, or actually at the papilla. I do not think there is any way of ruling out that possibility. It could of course, be in the head of the pancreas and the laws of probability would be all in our favor if we made such a diagnosis. I rather judge though that considering that she is at the present time described as poorly nourished they might have felt an epigastric tumor if it was cancer of the head of the pancreas. But if it is in the right place it does not have to be very large, so we cannot rule that out.

So far everything has run apparently smoothly enough until we come to the x ray examination of the stomach and there my troubles begin. They describe what seem to be two different lesions. One is in the greater curvature and is described as a notch. A notch might mean that it was something like a crater but they did not quite dare say it was a crater. It may mean only a localized irregularity. Would that be your interpretation, Dr. Holmes?

Dr. GEORGE W. HOLMES: Yes.

Dr. TRACY B. MALLOY: On the other side of the stomach, the lesser curvature there is a large deformity which they interpret as pressure from a mass outside the stomach. An interpretation of that sort could perfectly well be at fault, and it seems to me that one must consider the possibility that we are dealing here with a primary cancer of the stomach but there seems to be very little to go with it. The gastrointestinal symptoms are very slight, the stools show no occult blood, and there was no vomiting in the last illness which one would expect with a cancer as low down in the stomach as the antrum. I am more inclined to accept the x ray man's interpretation and say that was pressure from outside.

First, we have presumably, a rather large tumor mass pressing on the lesser curvature of the stomach and then we have something else deforming the greater curvature. I find it pretty hard to conceive of any single mass that could do both these things. It sounds to me more like two masses, and I would be tempted to believe that there is a mass in or on the under surface of the liver which is causing this deformity of the lesser curvature and that there

is something else perhaps in the region of the pancreas which is involving the greater curvature. These two masses might well be a cancer and its metastases. So again we come to the question of where the cancer is primary. It seems to me it is pure guesswork but I would like to place a first bet on its being primary in the gallbladder with metastases to the nodes at the head of the pancreas, the favorite place to which these cancers metastasize. Cancers of the gallbladder very often invade the liver directly without causing very much enlargement, which would also fit our story. We have to go back at this point, however, and consider the fact that the surgeon operated and did something which temporarily relieved the jaundice. If the gallbladder had been filled with cancer it hardly seems possible that by draining the gallbladder either externally or into the stomach that he could have relieved the jaundice. It is conceivable however that the viscus which was drained was not the gallbladder but was a dilated common duct which could have been anastomosed to the stomach or to the duodenum. In this case we must assume that it was not the primary cancer but its metastases which produced the obstruction.

I have tried to rule out cirrhosis as the primary disease and feel pretty confident about that. Whether there is any secondary liver pathology ought, I think, to be considered at least. There are a certain number of cases of obstructive jaundice associated with stones or malignancy in which one sees the development of an atrophy, a severe toxic necrosis of the liver. It is not inconceivable that she may have had a stone and that operation failed to cure her because she developed a secondary liver insufficiency. That, however, seems unlikely to me because cases of that sort in our experience here have almost always died very promptly after operation. Whether the necrosis in such cases is present before operation is hard to determine, but these cases die within two or three days as a rule rather than slowly petering out two or three weeks later. Another and more likely possibility is a mild biliary cirrhosis of the obstructive type, almost universal in cases of obstructive jaundice. I am prepared to pin all my faith on cancer somewhere in the biliary tract and my first bet in location is the gallbladder.

I would be very glad to hear some opinions from the clinicians.

DR CHESTER M JONES I agree with you that they are not going to find gallstones and cirrhosis. I think there is one other condition which is pretty rare, an obstructive type of inflammatory process involving the duct, and tissues around the duct too, which may result in jaundice. I do not know how it could be diagnosed except by exploration. We have had one or two cases here. It would be very hard to

see how any surgical treatment except possibly dilatation of the duct could give any relief. Dr Vincent, have you any suggestions?

DR BETH VINCENT None, except that obliterative cholangitis, which Dr Jones says occurs, would not account for the defect in the stomach.

DR JONES It reads very curiously here at the end of the x-ray report. It says "the remainder of the duodenum was normal." I wonder if the terminology was mixed up. Were they talking about the lower end of the duodenum? Having described nothing, they say the remainder is normal.

DR TRACY B MALLORY I could not tell from the report just what that meant and was forced to disregard it.

A PHYSICIAN Just assuming the surgeons did help, it is the only thing to bet on. I should say the obstruction is low in the common duct.

DR WILLIAM D SMITH As far as it goes, my first guess is that it is primary in the gallbladder.

DR TRACY B MALLORY Someone to fall with me. I guess we are ready for the axe to fall.

CLINICAL DIAGNOSIS

Carcinoma of the head of the pancreas?

DR TRACY B MALLORY'S DIAGNOSES

Carcinoma of the biliary tract, probably primary in the gallbladder.
Cholelithiasis

ANATOMIC DIAGNOSES

Papilloma of the papilla of Vater.
Biliary sinus (post-operative) communicating with the common bile duct.
Chronic cholecystitis with cholelithiasis and impacted stones in the cystic duct.
Obstructive cirrhosis.
Icterus.
Pulmonary emphysema.

PATHOLOGIC DISCUSSION

DR KENNETH MALLORY* There seem to be only two difficulties with your pathologist's clinical diagnoses. The first was the location of the tumor in this case. On inspecting the duodenum we found that the papilla of Vater was enlarged to about one centimeter in diameter. On opening it up we found a papillary mass arising in the ampulla, covering half the surface, and obstructing the ampulla pretty completely, although we could get a probe through it. We thought grossly it would turn out to be carcinoma, instead of which it proved to be a rapidly growing papilloma with no infiltration at the base at all. In addition there was dilatation of the bile ducts above the obstruction measuring one centimeter in diameter.

*Assistant Pathologist Boston City Hospital

There was a hydrops of the gallbladder. It was filled with mucoid material, stones and stones impacted in the cystic duct. Secondary to this there was a microscopic grade of biliary obstructive cirrhosis. We found proliferation of the bile ducts and slight increase in the surrounding fibrous tissue. Also there were obstruction and dilatation of the pancreatic ducts and some proliferation of the finer branches of the pancreatic duct. That is about all.

I think the x ray findings are rather misleading, because they lead one away from the diagnosis rather than help. I would have brought down the films but I was unable to find them.

A PHYSICIAN: What did the surgeon do? Cholecystostomy?

DR. KENNETH MALLORY: That would be my interpretation of the postmortem findings. At autopsy we found a sinus tract which hardly admitted a probe that led down into the common bile duct just above the ampulla.

I think this papilloma of the ampulla of Vater is rather rare. We have had carcinomas of course. Dr. Castleman showed me on case from your records here at the Massachusetts General which is also papilloma rather than cancer of the ampulla.

CASE 22162

PRESENTATION OF CASE

A twenty-seven year old American laborer was admitted complaining of shortness of breath.

Five months before entry the patient who had been perfectly well previously, suddenly coughed up a clot of blood about the size of a half dollar. A physician examined him and found nothing of significance. A specimen of sputum was examined and found to be negative. A week later following strenuous exertion he coughed up small quantities of bright red blood for about one hour. Another examination showed nothing, but an x ray done at this time was said to be negative for tuberculosis although some other process in the chest was noted. Subsequently the patient developed a persistent cough, usually brought on by exertion, which was productive of a small amount of blood tinged sputum. At scattered intervals he complained of dull pain in the left chest. Gradually dyspnea with exertion developed and occasionally he had wheezing respirations. Three months before entry he suffered a chill and a sharp pain in the left chest which was aggravated by respiratory movements. A physician made a diagnosis of pneumonia and he remained in a hospital for two weeks. During his acute illness he coughed up quantities of yellowish sputum, which was occasionally streaked with blood. He developed frequent night sweats which persisted up to his

admission. Following his recovery from the "pneumonia", dyspnea with moderate exertion became quite marked and he began to prop himself with pillows at night in order to sleep more comfortably. The cough continued and became dry and brassy in character.

Physical examination showed a well developed and nourished young man sitting propped up in bed with slight respiratory difficulty. The lips and fingernails were cyanotic. There was no generalized adenopathy but the epitrochlear nodes were palpable. The heart appeared to be displaced to the right and the apex impulse was in the fourth interspace, 6.5 centimeters from the midsternal line. The right border of cardiac dullness was 4.5 centimeters from the midsternal line. The heart sounds were normal. The examiner thought that the trachea was slightly deviated to the left. Chest expansion was limited on the left side. The left chest was dull to percussion anteriorly and posteriorly, and flat posteriorly beneath the angle of the scapula. Grocco's triangle was elicited although the side was not noted. Breath sounds and tactile fremitus were diminished to absent from above downward in the left chest. A few musical rales were audible bilaterally, more on the left side.

The temperature was 99°, the pulse 80. The respirations were 20.

Examination of the urine was negative. The blood showed a red cell count of 5,300,000, with a hemoglobin of 80 per cent. The white cell count was 17,100. 78 per cent polymorphonuclears. Several sputum examinations were negative for tubercle bacilli. A Hinton test was negative.

X ray examination showed the right side of the diaphragm and the right lung to be negative. The posterior two-thirds of the left leaf of the diaphragm was obscured. It was said to be definitely elevated at fluoroscopy. There was a triangular area of density with the shape of the lower lobe but about one third as large occupying the posterior and inferior portions of the left chest. Just above this triangle at the level of the lung root and slightly posterior to it was a rounded mass, 3 centimeters in diameter. This shadow contained no air. The heart and mediastinum were displaced toward the left. Several films taken at intervals previously during the patient's illness showed very little change in the size of the mass since the initial film but there was a progressive collapse of the left lower lobe and at one time the entire left lung was collapsed. Later films taken at expiration and inspiration showed hall valve occlusion of the upper lobe bronchus.

On the sixth day the patient had a chill and his temperature rose to 102°. The throat was found to be inflamed. This subsided promptly and two days later a bronchoscopy was done. This showed a firm whitish, roughly pyramidal

tumor mass about one inch below the carina in the left main bronchus. On the following day the patient had a temperature of 101.6° and coughed a great deal. Increased dullness was elicited in the left upper chest and bronchial breathing was audible in the upper chest posteriorly. No râles were present. The temperature rose to 103.2° on the following day but subsequently returned to normal and the patient remained comparatively comfortable. Following three administrations of pneumothorax, on the twenty-third hospital day a left thoracotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR FREDERICK T LORD The history of hemoptysis out of a clear sky is especially suggestive of pulmonary tuberculosis or of tumor. With the continuing decline in the number of cases of tuberculosis, tumor becomes relatively more common as a cause. Other possible causes of hemoptysis out of a clear sky are syphilitic ulceration of the trachea and bronchi, bronchiectasis and the rupture of tuberculous glands into the air passages. Echinococcus disease and *Distoma ringeni* would have to be considered as exotic causes. The wheezing suggests bronchial obstruction and it would be desirable to know its relation to posture and to cough and expectoration.

Assuming the presence of bronchial obstruction, the acute illness three months ago with chill, pain, cough and blood-streaked sputum may be ascribed to pneumonia arising in consequence of the trapping of infection behind an obstruction.

The brassy cough is difficult of explanation. It suggests the possibility of tracheal obstruction.

A biopsy on an enlarged gland may establish the diagnosis, but epitrochlear glands do not seem a likely site of metastasis.

The apparent displacement of the heart to the right is confusing and it would be desirable to know the site of maximum intensity of the heart sounds. It is unusual to have the heart displaced to the right and the trachea to the left.

Grocco's triangle of paravertebral dullness on the unaffected side is seldom of diagnostic value and least helpful in the presence of small pleural effusions where we most need assistance.

The signs in the left chest, dullness to flatness and diminished to absent breath sounds and tactile fremitus, though consistent with a small pleural effusion, are suggestive under all circumstances of a closed bronchus and consequent atelectasis.

DR TRACY B MALLORY We have no x-ray man here but I will ask Dr Churchill to show the films.

DR EDWARD D CHURCHILL The first x-ray

was taken September 3, 1935. Knowing what this abnormal area at the left hilum is, it is not fair to give the interpretation. This is a film of ours taken in February at the time of his admission. This is an expiration film taken the same day. There is quite a difference between the two films on full inspiration and full expiration.

DR LORD On comparison of the film at the end of full inspiration with that at the end of full expiration, it is evident that air enters the right side more readily than the left. On the left side in the region of the left border of the heart is a shadow with an unusually straight and sharply limited margin. This extends upward to the region of the left lung root. In the film during inspiration with the heart displaced to the right, the sharply limited shadow persists and suggests the presence of a collapsed left lower lobe.

DR CHURCHILL The swing in the mediastinum is rather interesting and may account somewhat for the confusing physical signs.

This is an x-ray taken after artificial pneumothorax.

DR LORD There is a small pneumothorax in the lower and a larger amount of air in the upper part of the left side, with an intervening area of lung extending to the chest wall. The appearance suggests an above and below a portion of the lung adherent to the chest wall.

DR CHURCHILL The x-ray interpretation suggested that in addition to the collapse of the lower lobe there was a trapping of air in the upper lobe. The upper lobe did not deflate with expiration as much as it should have.

DR LORD There is some asymmetry in the films. The trachea is about in the middle line and it is difficult to say whether it is displaced.

DR CHURCHILL Dr Hampton's interpretation was an obstructing lesion presumably represented by this opaque area at the left hilum which has not changed in size since September, and which he thought now had caused complete obstruction of the lower lobe bronchus with collapse of the lower lobe and probable partial ball valve obstruction of the upper lobe without collapse.

DR LORD Ball valve action seems more common with foreign body than with tumor, but at some time in the course of gradual encroachment on the bronchial lumen by an expanding tumor, inspiratory widening and expiratory narrowing of the passage may be expected to lead to the more ready entrance than exit of air and consequent pulmonary inflation.

It would be desirable, if possible, to know from the x-ray examination of any broadening of the carina. I cannot make out the bifurcation of the trachea on these films and it would be difficult to tell without the use of lipiodol. It would be desirable to have x-rays

of such other regions as the skull, spine and long bones. Was that done?

DR. CHURCHILL No

DR. LORD The presence of metastases would materially change the problem. Also, by bronchoscopy it would be desirable to determine the mobility of the trachea and bronchi.

In explanation of the bronchial breathing in the upper left chest behind, it may be due to a pneumonic process or to the persistence of atelectasis after the release of bronchial obstruction.

The statement that a tumor in the left primary bronchus has been established by bronchoscopy narrows the discussion. In addition there is atelectasis of the left lower lobe. There is likely also to be some bronchopneumonia of the left lower lobe, and there may also be bronchiectasis and abscess formation in the same region. By x ray he had obstructive emphysema of the left upper lobe.

It is of importance to remember with respect to the site of the tumor that, although it presents itself by bronchoscopy one inch below the bifurcation of the trachea, the origin of the tumor may arise from more remote bronchi and project upward into the lumen of the primary bronchus without attachment to the bronchial wall. There may thus be more space between the carina and the site of origin of the tumor than appears from the bronchoscopic description.

With respect to the nature of the tumor inflammatory narrowing is the most common cause of bronchial obstruction. Granulation tissue may, however, be dismissed as unlikely here. The chances are in favor of carcinoma. It may, however, be benign adenoma, a fibroma or polyp but I make the diagnosis of a malignant tumor of bronchial origin and that implies carcinoma. The next question is naturally with respect to metastases and x rays of other parts of the body would help. Metastases into the brain occur in about a quarter of such cases and into the adrenal in about a third, and may be scattered elsewhere. Months or even years may elapse without metastases and there is evidence from the investigation of Tuttle and Womack (*J Thoracic Surg*, Dec 1934) that malignant tumors of the major bronchi extend more slowly and are thus more amenable to surgery than those arising in the minor bronchi.

It is perhaps premature to discuss treatment, but I am tempted to do so in view of the statement that a thoracotomy was performed. As it is spoken of as thoracotomy without qualification, it was very likely an exploratory operation and by this means metastases may have been seen or felt in the pleural space and their presence or absence probably determined the question of further surgical procedure.

There is nothing but surgery which offers any considerable promise of success. X ray

treatment is not successful with deep-seated cancer, but may give temporary relief with lymphoblastoma. There are rare instances as in the case reported by Jackson and one by Arbuckle, in which bronchoscopic removal has been successful. Implantation of radium may be used in cases not amenable to surgery, but there is little to recommend the method and there is danger of a reaction from the radium beyond the region to which it is applied. Thus with malignancy surgery is the only promising expedient. Naturally in so difficult a problem as bronchial malignancy the operative mortality is high but otherwise there is only the prospect of a fatality.

DR. CHURCHILL The surgeon's hand was strengthened in this case by bronchoscopy, which gave a positive diagnosis of very rapidly growing carcinoma, thus, despite the fact that it is of five months' duration in a healthy appearing young man of twenty seven. The one disturbing feature about the case surgically was the observation by bronchoscopy that the growth extended one inch from the carina in the main stem bronchus. Dr. Lord has spoken of a tendency for cancers of the lung to grow from a tumor into a bronchus without invading the mucosa of the bronchial wall. It seemed quite possible that we were facing that situation. If there had been definite evidence of invasion of the bronchial wall within an inch from the carina, operation would not have been advised. A lantern slide will demonstrate an autopsy specimen from a patient that gave us this concept. This patient came to autopsy several months after pneumonectomy, having died of a local recurrence at the site of amputation of the bronchus and you see the thumb of tissue extending up the left main bronchus, passing the carina and extending into the trachea but showing no attachment to the bronchial mucosa until we come down to the main body of the tumor. So in approaching the operation on the patient we are now discussing, our problem was to anticipate just such a situation. Consequently, instead of putting a clamp or ligature around the left primary bronchus it was carefully divided with the knife and the "thumb" of tumor extracted from the bronchus.

This slide shows the lung when resected with the plug of tumor projecting from the left main bronchus. This is a closer view. This elongating ulcerating tumor had been described by the bronchoscopist as pyramidal in shape. This is the dissection of the lung and you can see the pus pouring out of the lower lobe as the plug of tumor was lifted upward relieving the obstruction.

The man died of infection. Due to manipulation of the infected lung and the ulcerating, necrotic tumor in the bronchus his pleural cavity became infected. On the third day it was drained as an empyema. In the presence of

fection the bronchial suture gave way so that an open communication between the free pleural cavity and the bronchus developed. A friction rub appeared over the precordium and he died on about the seventh or eighth day of fulminating sepsis, empyema, and mediastinitis. Physiologically he withstood the removal of the left lung. Infection, however, decided the issue.

CLINICAL DIAGNOSES

Carcinoma of the lung
Empyema

DR. FREDERICK T. LORD'S DIAGNOSES

Bronchiogenic carcinoma
Obstruction atelectasis
Obstruction emphysema
Bronchopneumonia?
Bronchiectasis?
Abscesses?

ANATOMIC DIAGNOSES

Carcinoma of the lung
Operative wound left pneumonectomy
Empyema, left
Pericarditis, acute serofibinous
Bronchopneumonia, confluent, right lower and middle lobes
Pulmonary edema right
Pleuritis, chronic fibrous, right apical, acute fibinous, left

PATHOLOGIC DISCUSSION

DR. MALLORY: I will pass around the specimen of resected lung. It shows very prettily a tumor mass, which is of considerable size, out in the parenchyma of the lung and the plug of tumor growing up the bronchus. The tumor apparently actually arose in a small bronchus near the apex of the lower lobe. It grew up the bronchus of the lower lobe and then up the primary bronchus passing across and partially obstructing in a ball valve fashion, as the clinical evidence shows, the bronchus to the upper lobe. So that it fulfills very completely the predictions of the x-ray department on that score. We have made sections of all of the hilar glands and they were completely free from tumor. We also made a number of sections of the wall of the primary bronchus and were unable to find invasion up to the point of section. There was one point where there appeared to be a slight

attachment of the tumor "thumb" to one of the smaller carinas and it had begun to pick up a new nourishment from that point but in the major bronchus it was entirely free.

A PHYSICIAN: What cell-type is it?

DR. MALLORY: That is not easy to say. It is an unusually undifferentiated tumor composed of very small, very uniform, rather round cells. They seem to be without question epithelial. I do not believe we are dealing with a lymphoma for a moment but it is not a typical epidermoid and it is not like the so-called oat cell tumor. The bronchus at one spot did show squamous cell metaplasia—a lesion which is possibly precancerous. In any case it is very surprising that with such a rapidly growing tumor the regional lymph nodes were free and we found no metastases elsewhere in the body.

The autopsy added comparatively little information. There was of course empyema and rather diffuse bronchopneumonia in the lung on the opposite side. There was some infection of the mediastinum and a septic pericarditis. Those are all the usual complications that would be feared in a case of this sort. We found no evidence of metastases although we had no permission to do the head. It is possible there may have been cerebral metastases.

DR. CHURCHILL: About the bronchoscopic biopsies, I have removed either one or more lobes or the entire lung in sixteen cases of tumor. In only nine of that number were there positive bronchoscopic biopsies. The impression given in a number of articles now is that bronchoscopy is the certain way to diagnose carcinoma of the lung. It is a certain way, but if you wait for positive bronchoscopic biopsies, you are going to miss a great many cancers of the lung at a time when it may be possible to do something for them surgically.

Of the sixteen cases five are living and apparently well, two patients received real palliative relief although they died subsequently of their disease, and seven died in the hospital subsequent to the operation. One patient died of widespread metastases, having experienced no real palliative relief and one patient with a benign tumor has been greatly relieved but will require additional surgery. In nine of this series of patients a total pneumonectomy has been performed. Four of these survived the operation and were discharged from the hospital, five died in the hospital.

THE CAUSE OF CORONARY DISEASE

THE long arm of coincidence is responsible for much medical folly—scientific as well as empiric. An alleged increase in the frequency of appendicitis has been ascribed to various causes, from the steel milling of wheat flour to the swallowing of raspberry pips. Many are the vagaries with which the unknown may be illuminated by an imaginative soul yet where in the evolution of intellect is a single concept or achievement devoid of imagination? Imagination is the fire of thought, it warms an otherwise wise barren outlook, it illuminates otherwise invisible possibilities. But imagination, like fire cannot be safely allowed out of control, when it destroys facts it must be stamped out when it threatens reason it must be all but extinguished. Coincidence is the first check to the apply to any imaginative conception it is the primitive correlation.

No subject is of more present speculative interest among medical doctors than that of coronary disease. All but the youngest of us have had our friends and contemporaries struck down

by it. All but the oldest of us are willing to follow any rational program of prevention—or to advise a rational program for others if it seems too arduous for personal practice. There is no lack of coincidences to lead us on, but life is too sweet to follow them all, and they are apt to contradict one another too.

It is perhaps only a coincidence that three Boston doctors have suggested within the past year that we might profitably steer in one general direction. Their observations have not been correlated studies but it would seem that they have unintentionally converged on the same general point from three different angles.

Dr. Timothy Leary has rather conclusively established coronary sclerosis as part of a more generalized metabolic disease akin to diabetes, and associated with cholesterol deposits in the subendothelial layers of the arteries.¹ He has, moreover, produced this type of "atherosclerosis" in rabbits by cholesterol feeding. He suggests that our coronary vessels may be exposed to these changes by two circumstances: 1. The inheritance of a weak cholesterol metabolism. 2. The overdosage with cholesterol containing food in the dietary.

Dr. Cadis Phipps has more recently published an analysis of contributory causes of coronary thrombosis.² He also mentions the possible influence of overeating not from the point of view of cholesterol dosage but as a general precipitating cause. In addition Phipps doubts that physical stress is a great factor, indeed he suggests a better future for the manual laborer with heart disease than for the white collar worker.

In this issue of the *Journal* (page 769) Dr. Francis P. Denny presents a statistical review of the death certificates for heart disease in Brookline, Massachusetts, since 1900. One sees therein an evolution of medical thought from the days when every murmur meant endocarditis, through the increasing recognition of "arteriosclerotic" and "hypertensive" heart disease to the present popularity of "coronary disease." Back of it all however, is the unambiguous increase in death from coronary disease. Denny's foremost speculation is that in sufficient or irregular muscular activity is the cause of this increase.

One might almost suspect that these three men had frequently lunched together in order to correlate their views before expressing them. Their views—based upon separate primitive coincidences—themselves coincide to give us a fairly direct hygiene for the prevention of coronary disease. The initial step in instituting this, as in all preventive hygiene is the choice of good heredity. Within the limits thus imposed we may further advise and practice dietary discretion, both qualitatively and quantitatively, as well as regularity of physical exercise. This latter should adjust itself to the

oxidation of the foodstuff eaten—particularly the fatty foodstuff eaten. Such hygiene might grow in wisdom with the years, and if it worked—ah, if it worked—what a relief it would be to hear less often that heart disease is the leading cause of death!

THE PROBLEM OF SILICOSIS

NEWSPAPER reports of the development of silicosis in large numbers of rock drillers in a West Virginia tunnel have recently called attention to the extent of this hazard in certain occupations which involve exposure to silica dust. In New York City it is estimated that at least 4,000 people, notably men engaged in the excavation of foundations and subway tunnels, are exposed to silica and other dust hazards, and the city Health Department is now studying means to reduce this exposure. Last winter the New York Legislature passed a workmen's compensation act, including silicosis among compensable occupational diseases.

Lanza and Vane have estimated that in the United States alone not less than 500,000 workers are, through their occupations, subject to a harmful exposure to silica dust. Metal mining, quarrying, stone-cutting and the foundry industry are the greatest sources of exposure, but potteries, glass works and such special processes as sand blasting, grinding, polishing and hard-rock drilling in coal mines contribute very materially to the production of silicosis. The losses from silicosis in terms of sickness and death are even more difficult to estimate, but it can be said with little fear of contradiction that silicosis now constitutes the greatest single occupational hazard in this country.

The causal relationship of constant exposure to rock dust to such conditions as "miner's phthisis" and "stonecutter's consumption" has been recognized for centuries but only recently has the distinction between silicosis and tuberculosis been generally accepted or the coincidence of the two diseases understood. Chiefly as a result of the investigations of members of the South African Institute for Medical Research and of Gardner at Saranac Lake the theory of mechanical injury from the inhalation of stone dust has been replaced by evidence of chemical action. Briefly, the minute silica particles retained in the air passages are ingested by wandering cells which in turn carry them to adjacent lymph nodes. In the body fluids, however, the silica is slightly soluble and toxic to the phagocytic cells. Many of the dust-laden cells are killed in this way and their load is

picked up by other cells. The silica also stimulates the fibroblasts with which it comes in contact, resulting in a scarring, first of the lymph nodes and perivascular structures, and finally in overgrowth and replacement of the respiratory epithelium.

Under working conditions the development of silicosis is dependent upon a number of variables, which can be measured only by highly technical procedures. Among the most important of these factors are percentage of free silica in the dust inhaled, number of particles per unit of air, size of particles inhaled, duration of exposure to silica dust, and susceptibility of the individual exposed. Experience has shown that massive exposure to dust high in silica, as in the manufacture of abrasive cleaning compounds, may produce disabling silicosis in a year or even less, while thirty-five years in a granite shed leaves a few cutters without even x-ray signs of pulmonary disease. Yet in most industries it is possible to estimate the hazard of silicosis with a degree of accuracy unusual in medical problems.

Uncomplicated silicosis is the most insidious of diseases. A slight dyspnea after perhaps fifteen or twenty years of exposure to dust is likely to be the first warning to the worker. Even then the condition tends to be slowly progressive and may not be disabling during the span of working life. The fibrosis, however, is an irreversible reaction and a process once established may progress to a fatal termination as long as fifteen or twenty years after exposure to silica has ceased. The real hazard from silicosis is the tuberculous infection which so frequently accompanies it and which is a menace to both the worker and his associates. Various studies indicate that from 25 to 50 per cent of silicotics also have tuberculosis and it is estimated that 75 per cent of all patients with silicosis die of tuberculosis.

That silicosis is not an abstract problem in Massachusetts was forcibly brought home to us two years ago by the report of the Special Industrial Disease Commission appointed by the General Court. X-ray and physical examination of representative groups of granite and foundry workers disclosed silicosis in 15 per cent and silicosis complicated by tuberculosis in 76 per cent of the former, compared with 88 per cent and 26 per cent respectively in the latter, and this represents the incidence among men actually at work. A study of mortality among granite cutters in two cities for a twelve year period showed a tuberculosis death rate ten times that among all males of twenty years and over in the same cities.

Although Massachusetts was one of the first states to declare silicosis a compensable disease, a worker discharged on account of a diagnosis of silicosis still has to prove physical disability

ity to entitle him to compensation, and his success is likely to depend on the medical and legal counsel he is able to employ. Compensation insurance rates for granite workers have risen to a level that has caused most Massachusetts employers to withdraw from their employees the protection of the Workmen's Compensation Act, which is not compulsory in this state. The unfortunate situation thus created applies to granite workers either disabled as a result of previous dust exposure or injured through industrial accident. The carefully worked out plan of the Industrial Disease Commission which aimed to reduce dustiness to safe levels, provide compulsory insurance coverage for hazardous occupations, with compensation for disabled and tuberculous workers and to detect pulmonary disease by periodic physical examinations at the hands of impartial examiners, was agreed upon in principle by employers, employees and insurance companies, yet no group was willing to make the concession necessary to put it into effect. Until labor and industry can make common cause against a mutual loss, medical science can do little toward the prevention of this greatest occupational disease.

CLEANLINESS NEXT TO GODLINESS

CLEANLINESS among school children, and the need for health instruction in cleanliness, is the thesis of Rowell and Tobey, publishing their views on the subject in the *American Journal of Public Health* (25 1237, [November] 1935). Godliness is not mentioned, even by inference. Various inadequacies in facilities for cleanliness now exist to greater or less degree, in the majority of American schools. Thus according to these authors in 1928 it was found from an investigation of 404 schools located in 22 states and the Dominion of Canada that in only 53.2 per cent of the buildings was hot water supplied in 80 per cent was some form of soap furnished and in 84.1 per cent were towels available.

Only 32 per cent of these schools, however, could comply with the American Child Health Association's standards of one lavatory to every 80 pupils, equipped with all three of the necessities—hot water, soap of sorts and towels, only 19.3 per cent complied with the requirements of the Massachusetts Institute of Technology specifying one lavatory to every 40 pupils, and only 5.7 per cent conformed to the Wood Rowell

standards of at least one lavatory, equipped with hot water, soap and towels, and conveniently located, to every 20 pupils.

Obviously, the lesson of cleanliness once learned cannot be practiced by the pupil and will not be carried home to a benighted family unless a reasonable opportunity is afforded of pursuing the laboratory course in the subject. The authors, however, go beyond an insistence on the mere motions of ablution. The quality of the soap should be within certain standards of excellence and should be adapted to the chemical nature of the water available in which regard the judgment of the average school janitor, excellent as it might be in other respects, should not be considered as necessarily of expert calibre. Soaps should be selected, then, with a view to their germicidal properties, their action on the skin, and their reaction with the water the general belief being that the purest soaps made from high quality fat and possessed of a relatively low content of free alkali, are the most germicidal.

The incidence of infectious disease has been reduced by many public health measures, still greater reduction, it is hoped, can be attained by the widespread practice of personal cleanliness.

SUCCESS

WHAT is success and who may attain it? Is the surgeon successful? Yes, though his case may have a fatal outcome, for he thoroughly trained in the intricacies of his technique, has given of his best.

And what of the pathologist who labors industriously painstakingly and unceasingly to discover that elusive germ, the deadly enemy of mankind, that causes some dread disease which one day will be but a bitter memory? Surely he is successful, though many hours of patient effort may seem a total loss. How often when he is most discouraged does he find that the solution has been almost within his grasp! He cannot and will not allow discouragement to turn him from his task, but will rather resolve to persevere that his goal may be attained.

Then too, there is the medical missionary, that remarkable contributor to medical service in Labrador Dr. Grenfell for example, who, with few resources and many handicaps, performs by saving the child whose life has been despaired of what seems to the anxious parents little less than a miracle. How often he is also rewarded by the lifelong gratitude of the man whose suffering has been almost intolerable or the woman who has gone through "the valley of the shadow of death."

And, of course, there is the general practitioner. His efforts are never-ceasing and though called upon to do much that demands unlimited

self-sacrifice he seldom receives an adequate recompense. But that does not deter him. He continues through many years of patient effort, and becomes the friend of all who know him.

May we not, then, say with truth that all whose efforts are honest, painstaking and productive of the best they have to offer, are successful? Not only physicians but nurses, technicians, and innumerable others may with propriety be included among those who justly claim success. Is it not the duty of all of us to co-operate in our daily tasks, performing them to the best of our ability and remembering that, though our success may seem very meager indeed, the result of our labors must of necessity help toward the advancement of that great science Medicine, which will continue in its development throughout all time.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

MCGINN, SYLVESTER A.B., M.D. Harvard University Medical School 1929. Assistant in Medicine, Massachusetts General Hospital, and St. Elizabeth's Hospital. Consultant, Sturdy Memorial Hospital. Address 270 Commonwealth Avenue, Boston, Mass. Associated with him is

WHITE, PAUL D. A.B., M.D. Harvard University Medical School 1911. Physician, Massachusetts General Hospital. Assistant Professor of Medicine, Harvard University Medical School. Address Massachusetts General Hospital Boston, Mass. Their subject is Progress in the Recognition of Congenital Heart Disease. Page 763.

DENNY, FRANCIS P. A.B., M.D. Harvard University Medical School 1895. Health Officer, Board of Health, Brookline, Mass. His subject is The Increase in Coronary Disease and Its Cause. Page 769. Address 111 High Street, Brookline, Mass.

TENNEY, BENJAMIN, JR. B.S., M.D. Harvard University Medical School 1925. F.A.C.S. Assistant Obstetrician, Massachusetts General Hospital and Cambridge Hospital. Junior Visiting Surgeon in Obstetrics and Gynecology, Boston City Hospital. Assistant in Obstetrics, Harvard University Medical School. His subject is A Clinical and Pathological Study of One Hundred and Fifty Cases of Tubal Pregnancy. Page 773. Address 309 Marlboro Street, Boston, Mass.

DARRAH, L. W. M.D. University of Pittsburgh School of Medicine 1911. Assistant Physi-

cian, Gardner State Hospital. His subject is Congenital Absence of the Vermiform Appendix in a Patient with Mental Disease. Page 776. Address East Gardner, Mass.

YOUNG, ALBERT G. B.S., Ph.D., M.D. Harvard University Medical School 1928. Formerly, Research Pharmacologist, University of Wisconsin, Assistant Professor of Pharmacology, University of Michigan, Assistant in Medicine, Boston City Hospital, Research Fellow in Medicine, Thorndike Memorial Laboratory, and Member of Medical Staff, Boston Dispensary. Now, Assistant Professor of Therapeutics, Boston University School of Medicine, and Member of Staff, Evans Memorial Hospital. His subject is The Occurrence of Allergic Reactions in Arthritic Patients. Page 779. Address 520 Commonwealth Avenue, Boston, Mass.

GRAVES, ROGER C. A.B., M.D. Syracuse University College of Medicine 1918. F.A.C.S. Urologist, Carney Hospital. Genito-Urinary Surgeon, Pondville Hospital. Member of the Associate Staff, New England Deaconess and Palmer Memorial Hospitals. Consulting Urologist, Quincy City Hospital, Lakeville State Sanatorium and Winchester Hospital. Genito-Urinary Consultant, Tumor Clinic, Boston Dispensary. Associate Consulting Urologist, Brockton Hospital. Address 12 Bay State Road, Boston, Mass. Associated with him is

KICKHAM, C. J. E. A.B., M.D. Harvard University Medical School 1927. Assistant Urologist, Carney Hospital, Assistant Visiting Urologist, Pondville Cancer Hospital at Norfolk. Associate Consulting Urologist, Quincy Hospital. Address 12 Bay State Road, Boston, Mass. Their subject is Congo Red for the Control of Bleeding. Page 782.

PETERSON, THOMAS H. A.B., M.D. Northwestern University Medical School 1926. F.A.C.S. Instructor in Orthopedic Surgery, Harvard University Medical School. Junior Visiting Surgeon, Boston City Hospital. Assistant Visiting Orthopedic Surgeon, Long Island Hospital. Associate Orthopedic Surgeon, New England Baptist Hospital. His subject is Method of Applying A Temporary Adhesive Support to the Back. Page 783. Address 23 Bay State Road, Boston, Mass.

FLOYD, CLEVELAND. M.D. Harvard University Medical School 1903. Physician-in-Chief, Division of Tuberculosis, Boston Health Department. His subject is A New Instrument An Anti-Adhesion Pneumothorax Needle. Page 785. Address 246 Marlboro Street, Boston, Mass.

POSTPARTUM HEMORRHAGE.

PART 2

If the uterus is carefully and continuously held after the birth of the baby, one knows definitely whether it is changing in size. If it is not changing in size and if there is no descent of the cord and no bleeding one knows definitely that the placenta is still attached. If this condition continues for one half to three quarters of an hour one begins to suspect the presence of an adherent placenta. If there has been descent of the cord and subsequent bleeding, one suspects that the placenta is separated and possibly retained. Now of course all adherent placentas are retained but not all retained placentas are adherent. The completely adherent placenta shows no evidence of bleeding. The retained placenta will show some evidence of bleeding and occasionally unusual bleeding, but if the fundus has been continuously held and is not overlarge, one knows that there is no concealed hemorrhage. I think there should be no worry as long as there is no real hemorrhage concerning a placenta that has not been delivered within an hour of the birth of the baby, and of course if there is no hemorrhage the length of time that the placenta remains in utero is not important, up to a certain point. However if there have been evidences of separation or if there is some bleeding and the placenta has not been delivered within one hour or one hour and a half, it is very wise to investigate the uterus. Thus of course, must be done under most careful asepsis, as entering the uterus after delivery is attended by a real risk of infection.

It is wise to have the patient anesthetized. One hand is put into the uterus, the other hand gives intelligent suprapubic pressure. If the placenta is a retained one and lying free in the uterine cavity behind a contracted os, the cervix is dilated and the entire placenta readily removed. It is rare that a case of this sort will bleed subsequently. It is consequently rare that in a case of this sort the uterus needs to be packed.

The adherent placenta offers a very different

problem. If it is completely adherent there will have been no hemorrhage, no bleeding. If it is partially adherent and partially separated there may have been a tremendous amount of bleeding. In either case the hand is thrust into the uterus and if one finds a partially separated placenta one readily recognizes the line of cleavage. If possible, the entire placenta should be removed in one maneuver. Those cases in which the placenta is partially separated may have bled and may bleed after the delivery of the placenta—so much so that packing the uterus is oftentimes a wise procedure. If the uterus has been packed the tamponade should be left in not over twenty-four hours and the fundus should be held so that one is certain that there is no bleeding behind the pack. If the adherent placenta is entirely adherent, one attempts to find the line of cleavage. This is usually possible but it is often impossible to remove all the placenta in one maneuver and these cases more often require packing than any other class.

Now there is one other type of retained placenta and that is the placenta accreta. The placenta accreta, if it is a complete placenta accreta, will give no bleeding at all. Upon investigation some line of cleavage is found but one soon appreciates that this line of cleavage stops. One realizes that the placenta is embedded in the uterine wall—a part of the uterus. As soon as this diagnosis has been made the proper procedure is abdominal section and hysterectomy. There is one type of accreta very infrequently seen in which the placenta practically covers the entire uterine wall. The thickness of the placenta may be practically no more than one-quarter inch. This, too, when the diagnosis is made demands hysterectomy.

Now it matters not whether a patient bleeds from a lacerated cervix or from the rupture of varicose veins or from a partially separated, adherent placenta or from an accreta. It does not matter what the cause of postpartum hemorrhage is. Loss of blood itself demands treatment. Postpartum hemorrhage very frequently requires transfusion and it is a very wise practice in any case of this sort to have an acceptable donor at hand before any operative procedures are instituted. Subsequent transfusions may be necessary, also intravenous glucose, elysis, the repeated use of intramuscular ergot and pituitrin and—par excellence—the use of morphine but once the source of the bleeding is diagnosed and controlled the treatment is the treatment of hemorrhage. It matters not whether this comes from a perforated gastric ulcer, a bleeding tonsil artery or a lacerated cervix. The treatment of postpartum hemorrhage, when the cause is diagnosed and the bleeding stopped, is the treatment of hemorrhage and that often means actual blood transfusion.

A PRIZE FOR AN APPROVED ESSAY

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding a rotating internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1935-1936.

This report is to be typewritten, and when completed is to be sealed, unsigned, in a plain envelope, which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope, and sent to

The Massachusetts Medical Society,
Committee on Medical Education and Medical
Diplomas
8 Fenway, Boston, Mass

The contest this year closes May 1, 1936. Reports may be submitted at any time prior to that date.

THIRD ANNUAL POSTGRADUATE MEDICAL
EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning April 19

Berkshire

Thursday, April 23, at 4 30 P M, at the House of Mercy Hospital, Pittsfield Subject Kidney and Bladder Diseases A (Medical)—Acute Nephritis — Etiology, Diagnosis and Treatment. Nephrosis and Its Treatment. Instructor W R Ohler Melvin H Walker, Jr, Chairman

Bristol North

Wednesday, April 22, at 7 30 P M, at the Morton Hospital, Taunton Subject Lung Diseases (Surgical)—(a) Empyema. (b) The Value of Surgery in Chronic Lung Diseases, Tuberculosis, Lung Abscess, etc Instructor R. H. Swett. Arthur R. Crandell, Chairman

Bristol South (New Bedford Section)

Friday, April 24, at 4 P M, at the St Luke's Hospital, New Bedford Subject Dermatology—Ten Common Skin Diseases—Diagnosis and Treatment (1) Impetigo Contagiosa, (2) Scabies, (3) Acne Vulgaris, (4) Psoriasis and Seborrheic Dermatitis, (5) Epidermophytosis, (6) Herpes Simplex and Zoster, (7) Eczema, (8) Erythema Multiforme, (9) Verruca Vulgaris and (10) Dermatitis Medicamentosa and Dermatitis Venenata Instructor John Adams, Jr Harold E Perry, Chairman

Franklin

Wednesday, April 22, at 8 00 P M, at the Franklin County Public Hospital, Greenfield Subject Cancer of the Stomach and Bowel Instructor L S McKittrick Halbert G Stetson, Chairman

Middlesex East

Wednesday, April 22, at 4 00 P M, at the Melrose Hospital, Melrose Subject Kidney and Bladder Diseases A (Medical)—Acute Nephritis — Etiology, Diagnosis and Treatment. Nephrosis and Its Treatment Instructor L H Hoyt Joseph H Fay, Chairman

Middlesex North

Friday, April 24, at 7 00 P M, at the Lowell General Hospital, Lowell Subject Arthritis Instructor F R Ober Leonard C Dursthoff, Chairman

Norfolk

Friday, April 24, at 8 30 P M, at the Norwood Hospital, Norwood Subject Lung Diseases—(a) Differential Diagnosis and Treatment of Lobar Pneumonia (b) The Surgical Problems of Empyema Instructors J H Pratt and J W Strieder H B C Riemer, Chairman

Worcester (Milford Section)

Wednesday, April 22, at 8 30 P M, at the Milford Hospital, Milford Subject Lung Diseases—(a) Differential Diagnosis and Treatment of Lobar Pneumonia (b) The Surgical Problems of Empyema. Instructors H F Newton and D S King Joseph I Ashkins, Sub-Chairman.

MISCELLANY

CONNECTICUT ITEMS

TRI CITY MEDICAL SOCIETY OF NORWICH, NEW LONDON, AND WILLIMANTIC, CONNECTICUT

The regular monthly meeting of the Tri City Medical Society of Norwich, New London, and Willimantic, Connecticut, was held Thursday, March 12, 1936, at Uncas-On-Thames, Norwich. Dr Richard Cattell of the Lahey Clinic, Boston, delivered an address on The Management of Surgical Diseases of the Colon and Rectum.

The principal manifestations of *ulcerative colitis* are diarrhea, fever, toxemia and an elevated white blood count. In the usual case, proctoscopic examination means establishing the diagnosis. These cases are poor surgical risks. Dr Cattell believes that any patient with an acute fulminating colitis who does not show early improvement should be operated upon. The disease is a medical condition first but if no relief is obtained medically, surgery should be resorted to. However, the operative mortality is high. Medical treatment is often very inadequate because of the anatomical changes caused by scarring due to loss of mucosa. The etiology of the disease has not been proved, but it probably is

a nonspecific infection which usually begins in the rectum. Ulceration may perforate and cause peritonitis. At the Lahey Clinic these cases are usually operated upon in several stages. A transverse ileostomy is done, followed in the second and third stages by removal of the colon. In a number of cases complete colectomies have been done with a cure of the condition. In 100 cases receiving early attention partial colectomy has eradicated the disease. However in most cases complete colectomy is necessary.

In considering differential diagnosis of colon lesions it is necessary to use digital examination, proctoscopic examination and x-ray of the colon. At the clinic, a double contrast air and barium enema has been found helpful.

The treatment of diverticulitis is essentially medical. In a few instances surgery becomes necessary. When this is the case it must be done in two stages: the first stage consisting in a colostomy or cecostomy above the lesion.

Polyps. Dr. Cattell says are the main etiological factor in carcinoma or malignancy of the large bowel and so any polyp discovered should be adequately treated. Usually these polyps can be cured by fulguration through the sigmoidoscope.

At the Lahey Clinic, where 500 cases of cancer of the rectum and colon have been carefully analyzed, it is felt that there is a good chance of a cure if properly treated. Early diagnosis is essential for good results. The best working rule is to do the most radical operation for the lesion that the patient will stand.

THE NEW LONDON COUNTY MEDICAL ASSOCIATION

At a meeting of this organization April 2 the following officers were elected for the ensuing year: Dr. William T. Driscoll of Norwich, Conn., President; Dr. Thomas Solts of New London, Conn., Vice-President; Dr. George H. Gilderalee of Norwich, Secretary-Treasurer; Dr. Charles G. Barnum of Groton, Conn., Councillor; Censors: Drs. Daniel Sullivan of New London, James J. Donohue of Norwich, and David Sussler of Norwich. State Delegates elected were: Drs. George H. Gilderalee and Albert C. Freeman of Norwich, and Drs. Richard Starr and Eldred Hendel of New London.

After the business meeting Dr. Charles F. Wilkin of Boston gave a most excellent informal talk on "The Economic Aspects of Medicine." A general discussion followed.

The meeting ended with a supper served by the Sanatorium.

DEATH

CHILDS.—HELEN SIMONDS CHILDS, M.D., aged eighty-four, died at Simsbury, Connecticut, April 8, 1936, at the home of her daughter, Mrs. John Schroeder, after a brief illness. A son also survives her.

Dr. Childs formerly practiced in Jamulca Plain, Massachusetts.

CHANCES IN THE FACULTY OF BOSTON UNIVERSITY SCHOOL OF MEDICINE

Dr. John Arthur Foley has been promoted from the position of Associate Professor of Medicine to Clinical Professor of Medicine and Dr. William Reid Morrison from the position of Assistant Professor of Surgery to Clinical Professor of Surgery.

FELLOWSHIPS AT THE HARVARD MEDICAL SCHOOL

Ten of the major fellowships at the Harvard Medical School totaling \$10,150 have been awarded for the next academic year as follows:

William O. Moseley, Jr., Traveling Fellowship for the study of medicine in Europe to Champ Lyons, assistant in bacteriology, Harvard Medical School, Harvard M.D. 1931.

William O. Moseley, Jr., Traveling Fellowship for the study of medicine in Europe to Louis H. Nason, M.D. 31 of Boston, Mass.

Edward Hickling Bradford Fellowship for medical research, to Alwin M. Pappenheimer, Jr., Ph.D. 32, has been at National Institute for Medical Research, Hampstead, London, England.

William Hunter Workman Fellowship for postgraduate study in this country or abroad to Theodore H. Ingalls, M.D. 33, New Hartford, Conn.

Jeffrey Richardson Fellowship for postgraduate study in this country or abroad to Benjamin V. White, Jr., M.D. 34, Summit, N.J.

James Jackson Cabot Fellowship for medical research to John H. Dingle, M.D., Kalamazoo, Mich.

John Warr Memorial Fellowship for medical research, to Richard L. Riley, M.D., Plainfield, N.J.

Charles Elliot Ware Memorial Fellowship for medical research to Emmanuel B. Schoenbach, M.D., New York City.

George Obeyne Shattuck Memorial Fellowship for medical research, to Israel Kaspnick, M.D., Providence, R.I.

DeLamar Student Research Fellowship to Charles B. Burbank, M.D., Miami, Fla.

AN ASSIGNMENT TO ATTEND THE MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY

Senior Surgeon Louis Schwartz, directed to proceed from New York, N.Y., on or about June 8, 1936, to Springfield, Mass., and return to attend the meeting of the Massachusetts Medical Society on June 8, 1936, and to present a paper on the subject of Industrial Dermatoses.

THE HOLYOKE BOARD OF HEALTH

A new board of health of the city of Holyoke has been appointed by the Mayor, consisting of Dr. Edwin M. Mahoney, Dr. Joseph A. Wonsak, and Mr. Arthur Habert.

The board organized with Mr. Habert, chairman, and Dr. Mahoney, secretary.
